Current version release details

Version	Effective date	Summary of changes
[2.0]	[16 June 2023]	Final guidelines following 2023 consultation

Note: There is a full version history at the end of this document.

AEMO | [16 June 2023] Page 4 of 78

1. Introduction

1.1. Purpose and scope

These are the Power System Model Guidelines (**Guidelines**) made under clause S5.5.7(a)(3) of the National Electricity Rules (**NER**). They specify AEMO's requirements concerning the information and models that *Generators, Integrated Resource Providers* (**IRPs**), *Network Service Providers* (**INSPs**), *Network Users, Market Network Service Providers* (**MNSPs**), *Network Support and Control Ancillary Services* (**NSCAS**) tenderers and prospective providers of system restart ancillary services (**SRAS Providers**) (**Applicants**) must provide to AEMO and NSPs in specified circumstances.

AEMO requires this information and models to develop mathematical models for plant, including the impact of their *control systems* and protection systems on *power system security*.

These Guidelines have effect only for the purposes set out in the NER. The NER and the *National Electricity Law* prevail over these Guidelines to the extent of any inconsistency.

1.2. Definitions and interpretation

1.2.1. Glossary

The words, phrases and abbreviations in Table 1 have the meanings set out opposite them when used in these Guidelines.

Terms defined in the *National Electricity Law* and the NER have the same meanings in these Guidelines unless otherwise specified in this Section 1.2.1.

Terms defined in the NER are intended to be identified in these Guidelines by italicising them, but failure to italicise a defined term does not affect its meaning.

Terms defined in new rules to take effect after the date of publication of these Guidelines have the meaning given in the relevant amending rule and in any applicable transitional provisions in the NER prior to their commencement. Such terms are also intended to be identified in these Guidelines by italicising them, but failure to italicise a defined term does not affect its meaning.

Table 1 Defined terms

Term	Definition
Applicants	Generators, Integrated Resource Providers, Network Service Providers, Network Users, Market Network Service Providers, prospective Network Support and Control Ancillary Services tenderers and prospective system restart ancillary services providers to whom these Guidelines apply.
AGC	automatic generation control
AVR	automatic voltage regulator
BFP	boiler feed-pump
Composite load model	A mathematical representation of a load based on separation into explicit components with generic parameterised descriptions. An example is the CMLDxx family of models in PSS®E
СТ	Current Transformer
Data Sheets	Power System Design Data Sheets and Power System Setting Data Sheets
DC	direct current

AEMO | [16 June 2023] Page 5 of 78

Disturbance Any, or a combination of the following: A balanced or unbalanced fault remote from a connection point. A balanced or unbalanced fault at, or close to, a connection point. A balanced or unbalanced fault at, or close to, a connection point. A trip, with or without a fault, of one or more production units (from the same, or another or the point setting) or this ping. A trip, with or without a fault, of one or more production units (from the same, or another or close to voltage collapse). A short or lang voltage disturbance (e.g., as could occur when a part of the network is islanded). Rapid, large changes in the energy source available to the plant (e.g., as could occur when a count or count of the generaling system or integrated resource system. 1.2.2. Interpretation

The following principles of interpretation apply to these Guidelines unless otherwise expressly indicated:

(a) These Guidelines are subject to the principles of interpretation set out in Schedule 2 of the *National Electricity Law*.

AEMO | [16 June 2023] Page 7 of 78

(b) The words "includes", "including" or "such as" are not words of limitation, and when introducing an example, do not limit the meaning of the words to which the example relates to examples of a similar kind.

1.4. Context

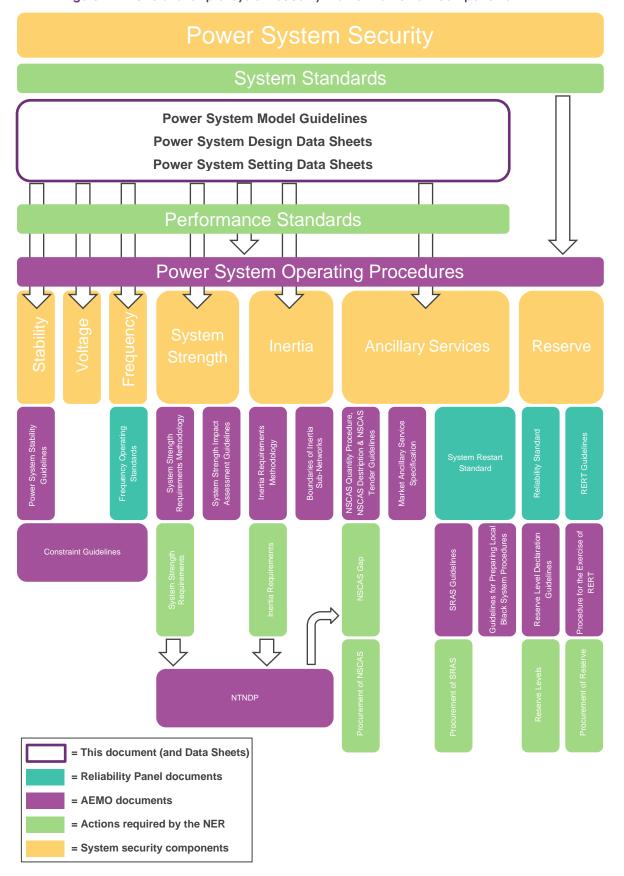

These Guidelines and the Data Sheets are tools that enable AEMO and the NSPs to implement a number of obligations under the NER, especially those that relate to meeting AEMO power system security responsibilities and the management of new connections to the national grid.

Figure 1 shows the interrelationship between these Guidelines and other NER instruments and AEMO guidelines, operating procedures and activities. By no means a complete depiction, it highlights the criticality of compliance by affected *Registered Participants* with these Guidelines by showing how they relate to key obligations imposed on AEMO and NSPs in the context of *power system security*.

AEMO | [16 June 2023] Page 9 of 78

Figure 1 Interrelationship of System Security Market Framework components

AEMO | [16 June 2023] Page 10 of 78

2. Provision of models and other information

AEMO needs to be able to model *power system* behaviour on an ongoing basis to ensure that it can fulfil its obligations to operate the *power system* in accordance with the NER. To achieve this, AEMO needs up-to-date information about the behaviour of *plant* connected to the *power system*. *Generators* and *Integrated Resource Providers* should ensure that all models and other information provided to AEMO in accordance with these Guidelines remain up to date, because if AEMO reasonably considers that:

- the analytic parameters for modelling of a *generating system* or *integrated resource system* are inadequate; or
- available information, including results from a test of a generating system or integrated resource system under NER 5.7.6(a), are inadequate to determine parameters for an applicable model,

AEMO may direct an NSP to require a *Generator* or *Integrated Resource Provider* to conduct a test under NER 5.7.6(a) at the *Generator*'s or *Integrated Resource Provider*'s cost.

Furthermore, a *Generator* or *Integrated Resource Provider* who has previously provided adequate root mean square (**RMS**) models and associated information to AEMO will be required to provide up-to-date electromagnetic transient (**EMT**) models to AEMO if required by an NSP who carries out a *system strength impact assessment*.

2.1. Generators

The circumstances in which *Generators* must provide models and other information to AEMO and relevant NSPs in respect of their *generating systems* under these Guidelines are specified in NER S5.5.7(b1)(1)(i) and are, in summary:

Rec	quireme	ent		Timing
(a)	will: (1) a re (2) a	adversely eliability adversely	s, in AEMO's reasonable opinion, a risk that a Generator's plant or affect network capability, power system security, quality or of supply, inter-regional power transfer capability; or affect the use of a network by a Network User, or adverse system strength impact ¹ .	Within 20 business days of AEMO's notice of the impact described in sub-paragraph (1), (2) or (3).
(b)	NER S		MO's reasonable opinion, information of the type described in required to enable an NSP to conduct a system strength impact	Within 15 <i>business days</i> of AEMO's request to provide the relevant information.
(c)	which (1) a	perform affect the equireman on AEMO	nerator is proposing an alteration to a generating system for ance standards have been agreed and the alteration will: generating system's performance relative to any of the technical ents in NER S5.2.5, S5.2.6, S5.2.7 and S5.2.8; or is reasonable opinion: have an adverse system strength impact; or adversely affect network capability, quality or reliability of supply, inter-regional power transfer capability or the use of a network by another <i>Network User</i> ³ .	Within 20 business days of AEMO's notice of the impact described in sub-paragraph (1) or (2).

¹ See NER 5.2.5(d). See also footnote 2 for further information about *system strength impact assessments*.

AEMO | [16 June 2023] Page 11 of 78

² See NER 5.2.5(e). Where a *Generator* has previously provided an RMS model to AEMO, that model will be inadequate for carrying out a full *system strength impact assessment* and an EMT model will be required. For further information about full *system strength impact assessments*, see the System Strength Assessment Guidelines.

³ See NER 5.3.9(b)(2).

Rec	quirement	Timing
(d)	When negotiating a connection agreement ⁴ .	With the application to connect submitted under NER 5.3.4.
(e)	When connecting a generating system <30 megawatts (MW), or generating units totalling <30 MW to a connection point on a distribution network ⁵ .	With the application to connect submitted under NER 5.3.4.

It is recognised that an augmentation to an existing *generating system* proposed by a *Generator* may be captured as a material alteration under (c) above and require the provision of models for the entire *generating system* conforming with these Guidelines, even where the existing legacy plant and equipment within the *generating system* is not itself altered. Further guidance on this matter is provided in Section 4.8.4 below.

2.2. Integrated Resource Providers

[Note: references in this section 2.2 are to the NER in effect on the *effective date* as defined in NER 11.145.1⁶, or as subsequently amended.]

The circumstances in which *Integrated Resource Providers* must provide models and other information to AEMO and relevant NSPs in respect of their *integrated resource systems* under these Guidelines are specified in NER S5.5.7(b1)(1)(i) and are, in summary:

Rec	uirement	Timing
(a)	 Where there is, in AEMO's reasonable opinion, a risk that an <i>Integrated Resource Provider's</i> plant will: (1) adversely affect network capability, power system security, quality or reliability of supply, inter-regional power transfer capability; (2) adversely affect the use of a network by a Network User; or (3) have an adverse system strength impact⁷. 	Within 20 <i>business days</i> of AEMO's notice of the impact described in sub-paragraph (1), (2) or (3).
(b)	Where, in AEMO's reasonable opinion, information of the type described in NER S5.2.4 is required to enable an NSP to conduct a system strength impact assessment ⁸ .	Within 15 <i>business days</i> of AEMO's request to provide the relevant information.
(c)	Where the Integrated Resource Provider is proposing an alteration to a integrated resource system for which performance standards have been agreed and the alteration will: (1) affect the integrated resource system's performance relative to any of the technical requirements in NER S5.2.5, S5.2.6, S5.2.7 and S5.2.8; or (2) in AEMO's reasonable opinion: (A) have an adverse system strength impact; or (B) adversely affect network capability, quality or reliability of supply, inter-regional power transfer capability or the use of a network by another Network User ⁹ .	Within 20 business days of AEMO's notice of the impact described in sub-paragraph (1) or (2).

AEMO | [16 June 2023] Page 12 of 78

⁴ See NER S5.2.4.

⁵ See NER S5.5.6.

⁶ As at the date of this publication, the date on which Schedules 1-6 of the *National Electricity Amendment (Integrating energy storage systems into the NEM) Rule* 2021 come into effect.

⁷ See NER 5.2.5A(d). See also footnote 7 for further information about *system strength impact assessments*.

⁸ See NER 5.2.5A(e). Where an Integrated Resource Provider has previously provided an RMS model to AEMO, that model will be inadequate for carrying out a full system strength impact assessment and an EMT model will be required. For further information about full system strength impact assessments, see the System Strength Assessment Guidelines.

⁹ See NER 5.3.9(b)(2A).

Rec	uirement	Timing
(d)	When negotiating a connection agreement ¹⁰ .	With the application to connect submitted under NER 5.3.4.
(e)	When connecting a <i>bidirectional unit</i> smaller than 5 MW or <i>bidirectional units</i> totalling less than 5 MW to a connection point to a distribution network ¹¹ .	With the application to connect submitted under NER 5.3.4.

2.3. Network Service Providers

The circumstances in which NSPs must provide models and other information to AEMO and any other relevant NSPs in respect of their *network elements* under these Guidelines are specified in NER S5.5.7(b1)(1)(ii) and are, in summary:

Rec	quirement	Timing
(a)	 Where there is, in AEMO's reasonable opinion, a risk that an alteration to a network element or the connection of any new or additional equipment to the network will: (1) adversely affect network capability, power system security, quality or reliability of supply, inter-regional power transfer capability; or (2) adversely affect the use of a network by a Network User¹². 	Within 20 <i>business days</i> of AEMO's notice of the impact described in sub-paragraph (1) or (2).
(b)	 Where there is, in AEMO's reasonable opinion, a risk that an NSP's <i>plant</i> or equipment will: (1) adversely affect network capability, power system security, quality or reliability of supply, inter-regional power transfer capability; (2) adversely affect the use of a <i>network</i> by a <i>Network User</i>, or (3) have an adverse system strength impact¹³. 	Within: • 20 business days of AEMO's notice of the impact described in subparagraph (1) or (2); or • 15 business days of AEMO's notice of the impact described in subparagraph (3).
(c)	Where, in AEMO's reasonable opinion, information of the type described in NER 4.2.4(o) is required to enable another NSP to conduct a <i>system strength impact assessment</i> ⁴ .	Within 15 <i>business days</i> of AEMO's request to provide the relevant information.

2.4. Network Users

The circumstances in which *Network Users* must provide models and other information to AEMO and relevant NSPs in respect of their *plant* under these Guidelines are specified in NER S5.5.7(b1)(1)(iii) and are, in summary:

Re	Requirement		Timing
(a)		ere there is, in AEMO's reasonable opinion, a risk that a <i>Network User's</i> at will: adversely affect network capability, power system security, quality or reliability of supply, inter-regional power transfer capability; adversely affect the use of a <i>network</i> by a <i>Network User</i> ; or have an adverse system strength impact ¹⁵ .	Within: • 20 business days of AEMO's notice of the impact described in subparagraph (1) or (2); or • 15 business days of AEMO's notice of the impact described in subparagraph (3).

¹⁰ See NER S5.2.4.

AEMO | [16 June 2023] Page 13 of 78

¹¹ See NER S5.5.6A.

¹² See NER 4.3.4(o).

¹³ See NER 5.2.3(j).

¹⁴ See NER 5.2.3(k).

¹⁵ See NER 5.2.4(c).

Red	quirement	Timing
(b)	Where, in AEMO's reasonable opinion, information of the type described in NER S5.3.1(a1) is required to enable an NSP to conduct a <i>system strength impact assessment</i> ¹⁶ .	Within 15 <i>business days</i> of AEMO's request to provide the relevant information.
(c)	Before connecting any new or additional equipment to a <i>network</i> ¹⁷ .	With the application to connect submitted under NER 5.3.4.

It is recognised that an augmentation to a *Network User's* existing installation may be captured under (c) above and require the provision of models for the entirety of the *Network User's* equipment conforming with these Guidelines, even where the existing legacy plant and equipment within the installation is not itself altered. Further guidance on this matter is provided in Section 4.8.4 below.

2.5. Market Network Service Providers

The circumstances in which MNSPs must provide models and other information to AEMO and relevant NSPs in respect of their *plant* or equipment under these Guidelines are specified in NER S5.5.7(b1)(1)(iv) and are, in summary:

Rec	quirement	Timing
(a)	 Where there is, in AEMO's reasonable opinion, a risk that MNSPs' <i>plant</i> or equipment will: (1) adversely affect network capability, power system security, quality or reliability of supply, inter-regional power transfer capability; (2) adversely affect the use of a <i>network</i> by a <i>Network User</i>; or (3) have an adverse system strength impact¹⁸. 	Within: 20 business days of AEMO's notice of the impact described in sub-paragraph (1) or (2); or 15 business days' of AEMO's notice of the impact described in sub-paragraph (3).
(b)	Where, in AEMO's reasonable opinion, information of the type described in NER S5.3a.1(a1) is required to enable an NSP to conduct a <i>system strength impact assessment</i> ¹⁹ .	Within 15 <i>business days</i> ' of AEMO's request to provide the relevant information.
(c)	In respect of the proposed alteration to connected plant ²⁰	With the application submitted under NER 5.3.12
(d)	Before <i>connecting</i> any new or additional equipment to a <i>network</i> ²¹ .	With the application to connect submitted under NER 5.3.4.

2.6. NSCAS tenderers

The circumstances in which *NSCAS* tenderers must provide models and other information to AEMO in respect of their *plant* or equipment under these Guidelines are specified in NER S5.5.7(b1)(1)(v), namely when tendering to provide *NSCAS* under NER 3.11.5²². The models and information must be provided to AEMO with an *NSCAS* expression of interest.

¹⁶ See NER 5.2.4(d).

¹⁷ See NER S5.3.1(a1).

¹⁸ See NER 5.2.3A(a).

¹⁹ See NER 5.2.3A(b).

²⁰ See NER 5.3.12(b)(2)

²¹ See NER S5.3a.1(a1).

²² See NER 3.11.5(b)(5).

2.7. Prospective SRAS Providers

The circumstances in which prospective *SRAS Providers* must provide models and other information to AEMO in respect of their *plant* or equipment under these Guidelines are specified in NER S5.5.7(b1)(1)(vi), namely when tendering to provide *SRAS* under NER 3.11.9²³. The models and information must be provided to AEMO with a tender for the provision of *SRAS* or, where AEMO makes a direct request for an offer for the provision of *SRAS*, in response to that request.

3. Models and data requirements

Changing *plant* technology in the *power system* has increased the need for AEMO and NSPs to have a deeper understanding of all equipment connecting to the grid, including smaller *plant*, which in aggregate, can affect the *power system security* and *reliability*.

3.1. Generators, Integrated Resource Providers, NSPs, and MNSPs

On each occasion that a *Generator, Integrated Resource Provider*, NSP, or MNSP is required under the NER to provide models and other information to AEMO and an NSP²⁴, they must provide:

- · Completed Data Sheets;
- Site-specific RMS models of all plant that comply with these Guidelines, including:
 - Model block diagrams; and
 - Model source code:
- Site-specific EMT models of all *plant* that comply with these Guidelines;
- A releasable user guide (RUG) for both RMS and EMT models in the template specified in the Releasable User Guide Template²⁵; and
- R2 test report, and pre-commissioning model confirmation test report²⁶.

3.2. Network Users and loads

On each occasion when a *Network User* is required under the NER to provide load dynamic models and other information to an NSP, they must provide either of the following two categories of load models:

• Generic IEEE ZIP load models, or Composite load models, with the model parameters selected appropriately based on the configuration of the *Network User's* facility; or

AEMO | [16 June 2023] Page 15 of 78

²³ See cla NER use 3.11.9(g).

²⁴ In the case of models and information required to be provided by an NSP, this is to be read as providing them to another NSP.

²⁵ Note that AEMO expects the Releasable User Guide Template to be *published* prior to the expiry of the consultation on this document.

²⁶ Depending on the expected impact of the *plant* on the *power system*, pre-commissioning model confirmation results may be required before the *connection* can proceed.

- Site-specific detailed RMS and EMT models of the Network User's facility that comply with these Guidelines, including documentation as below:
 - Model block diagrams; and
 - Model source code;

The following supplementary documents must be provided along with the load models:

- Completed Data Sheets;
- A RUG for RMS and EMT models where site-specific detailed models are required; and
- Model block diagrams and source code where site-specific detailed models are required.

A *Network User* may be exempted from providing load dynamic models, subject to the assessment of AEMO and the NSP, on a project-specific basis. Such an assessment should be conducted, considering the load size, the applied technology, and potential adverse impact on other *Registered Participants* and power system operation, for example, in accordance with the System Strength Impact Assessment Guidelines where applicable..

3.3. NSCAS tenderers and SRAS Providers

On each occasion that an *NSCAS* tenderer or prospective *SRAS* Provider is required to provide models and other information to AEMO, they must provide the models and other information specified in Section 3.1 except where they:

- have provided the necessary models and information to AEMO within the previous three years and AEMO had indicated at the time these were acceptable;
- are not proposing to make any changes to the components of the plant or proposed facility
 within the intended period of any proposed agreement for the provision of NSCAS or SRAS
 (as applicable); and
- no changes are likely to occur to the operation of plant (regardless of whether they are
 owned by the relevant NSCAS tenderer or prospective SRAS Provider) that will impact the
 proposed NSCAS or SRAS (as applicable) within the intended period of any proposed
 agreement for the provision of NSCAS or SRAS (as applicable),

AEMO may require further clarifications on the models or information previously provided, in which case the relevant *NSCAS* tenderer or prospective *SRAS* Provider will need to respond within any timeframe requested by AEMO at the time.

3.4. Exemptions

The requirements in these Guidelines will apply for all *power system* conditions and model types, but there are circumstances where AEMO and an NSP may exempt an Applicant from having to provide the full complement of models and other information specified in Sections 3.1 or 3.2 (as applicable). Table 3 details the circumstances where AEMO and the NSPs may exempt an Applicant.

Table 3 Grounds on which exemption may be granted

Conditions	Reasoning	Exemption
Plant size is ≤5 megavolt amperes (MVA) and the	Impact of the proposed <i>plant</i> on <i>network</i> and surrounding <i>plant</i> would be minimal.	EMT model not required.

AEMO | [16 June 2023] Page 16 of 78

Conditions	Reasoning	Exemption
connection point's aggregate short circuit ratio (SCR) ^A > 10	Proposed <i>plant</i> unlikely to be impacted by low system strength.	
Plant size < 1 MVA	Impact of the proposed <i>plant</i> on <i>network</i> and surrounding <i>plant</i> would be insignificant.	No modelling information required.

A. As assessed by the connecting NSP accounting for all nearby plant that can reasonably impact SCR at the connection point under consideration.

Applicants whose *plant* meets the conditions specified in Table 3 need not apply to AEMO for exemption unless their connecting NSP requires them to do so. Applicants who consider that they qualify for exemption from having to provide the full complement of models and other information must approach their connecting NSP to seek advice on whether an application for exemption is required. If advised by the connecting NSP that it is, the Applicant must apply for exemption to AEMO and the connecting NSP using the form contained in Appendix A.

Following consideration of an application for exemption, AEMO must:

- · Accept or reject it;
- · Propose options for the Applicant to consider; or
- · Request further information.

4. Model adequacy

AEMO and NSPs use *plant* models for many purposes. The assessment of the suitability of proposed *plant* and its proposed *performance standards* and determination of *plant* capability to achieve its *performance standards* are the ones that most *Registered Participants* are aware of, and is the main reason why they must provide models, but this is just one of many. Others include the ongoing management and assessment of *power system security*, such as short-term operational planning and development of *constraint* equations, stability assessment, use in long-term *power system* planning, the assessment of other proposed connections, procurement of *ancillary services*, simulations for the purpose of training and incident investigations.

For these reasons, models must demonstrate the degree of adequacy and accuracy specified in these Guidelines.

For each *plant* being assessed, the Applicant must provide a site-specific model in the appropriate tool and consisting of components necessary to facilitate accurate studies for the specific phenomenon under consideration.

Subject to any requirements specified elsewhere in these Guidelines, it is expected that models provided to AEMO and NSPs are an accurate representation of *plant* and *plant* responses for multiple, successive Disturbances. This does not require those providing models to consider every conceivable combination of Disturbances. For example, when submitting models for the purpose of connection studies, the submitting party can evaluate responses to singular or limited combinations of Disturbances only to the extent that they are relevant to the *access standard* being considered. Appendix C outlines the physical components to be included in a model based on the studies being performed. As load flow and fault level studies are typically based on Newtonian solution methods, rather than physical components, these study types are excluded from the tables in Appendix C.

Due to the continuous evolution of technology, the tables in Appendix C may not cover every key component present in all *plant*. If a *plant* or component not specified in those tables is

AEMO | [16 June 2023] Page 17 of 78

determined by AEMO and the NSP to provide a significant contribution to the result of a study, AEMO and the NSP may request that this *plant* or component be included in the model submitted by the Applicant.

4.1. Load flow model requirements

Adequate load flow models must represent the *plant* steady state conditions for the full operating envelope in the software package nominated by AEMO and the NSP.

Where applicable and where the RMS tool allows, load flow models of plant must include:

Table 4 Load flow model inclusions

Plant element	Including
Generating or bidirectional units ^A , reactive	MVA base
support <i>plant</i>	Source impedance, including positive, negative and zero sequence
	Active and reactive power profile ^B
	Voltage control scheme
	Active / reactive power capability curve in PSS®E .gcp (preferred) or text format
Plant transformers ^A (including step-up,	MVA base and ratings
intermediate and connection point)	Winding vector group
	All winding voltages
	Winding impedances, including positive, negative and zero sequence
	Grounding arrangements and impedances
	Connection code
	Magnetising impedances
	Tap location, number and voltage range
	Voltage control scheme
HVDC links	Plant ratings, voltages and impedances
	Control modes, including target control quantities
	Base voltages levels and target voltage levels
	Transformer impedances, voltages, tap ranges, bases
	Firing angle ranges (for applicable technologies)
	Commutating impedances (for applicable technologies)
Reticulation network ^A	Positive, negative and zero sequence impedance
Shunt components	Switched shunts
	Fixed shunts
	Switched shunt voltage control scheme
Loads	Active and reactive power levels, in most appropriate format (power / impedance / current)

A. For *plant* consisting of several distributed *production units*, aggregation principles outlined in Section 4.7 must be used. B. Consistent with the plant's performance standard

The load flow model contents must be consistent with the information provided by the Applicant in the RUG.

4.1.1. Format

Section 4.3.11 outlines the model format requirements for load flow models when represented in RMS simulation tools.

AEMO | [16 June 2023] Page 18 of 78

4.2. Fault level model requirements

Provision of short circuit data for the *plant* to IEC 60909:2016 is sufficient to meet the requirement for short circuit analysis. This short circuit data should be integrated into the load flow model to the extent this is possible in the host software platform.

4.2.1. Format

Section 4.3.11 outlines the model format requirements for fault level models when represented in RMS simulation tools.

4.3. RMS and EMT stability model requirements

The following criteria apply before an RMS or EMT model can be accepted for assessment by AEMO and the NSP. The requirements specified in this section apply to all *plant* except those in Section 4.3.2, which only apply to *plant* participating in the frequency control ancillary services (**FCAS**) market or the provision of other forms of *frequency* control, such as in a future fast frequency response market.

4.3.1. General requirements

Transient models provided under NER S5.2.4(b) must define the site-specific electromechanical and *control system* performance of components comprising *plant* under Steady State, set-point change and Disturbance conditions for all levels of system strength and energy source availability that the *plant* is rated to operate.

That plant includes:

- The production unit or any other primary or relevant secondary plant within the generating system or integrated resource system that may affect the overall interaction (active power, reactive power or voltage) of the generating system or integrated resource system with the power system (e.g. reactive power compensating plant).
- Any dynamic *reactive power* or *voltage* compensation *plant* within the *network* that can have an impact on transient and *voltage* stability.

Parameters of transient models developed for new and modified *generating systems* or *integrated resource systems* (including any supervisory control) should be refined through extensive connection studies. *Plant* model and parameters must be assessed through the NSP and AEMO due diligence process to be qualified as R1 data.

RMS and EMT models and parameters submitted to AEMO and the NSP must conform to the following general requirements before being considered for assessment.

Model compatibility and stability

Models must:

- Be compatible with the power system software simulation products specified by AEMO and the NSP;
- Work for a range of dynamic simulation solution parameters rather than for specific settings only;
- Be numerically stable for the full operating range including a wide range of grid SCR and grid and fault X/R ratio;

AEMO | [16 June 2023] Page 19 of 78

- any model validity limitations due to system impedance or strength should be clearly defined within the RUG;
- Be numerically stable up to a simulation time of up to five minutes (have voltage, frequency, active power and reactive power remaining constant for dynamic simulation runs with no Disturbance); and
- Not show characteristics that are not present in the actual *plant* response.

Model composition and operating range

Models must:

- Be a model of the specific *plant* being considered;
- Include any relevant non-linearities, such as limits, arithmetic or mathematical functions, deadbands or saturation;
- Represent the generating system or integrated resource system and reactive compensation
 plant performance for all possible Steady State output and system strength levels where the
 plant would be in operation;
- Represent *plant* response for set-point changes including *active power*, *reactive power*, *power factor*, *voltage* and *frequency*, including associated *ramp rates*;
- Represent the generating system or integrated resource system and reactive compensation
 plant performance for all possible values of energy source variation where the generating
 system or integrated resource system would be in operation;
 - For generating units or bidirectional units with an inherently variable power source, the ability to vary the energy source strength must be maintained throughout the simulation study;
- Represent all *plant* within the *generating system* or *integrated resource system*, including *generating units*, *bidirectional units*, governors, park controllers, *tap-changing transformers*, and *reactive power* compensating *plant*;
 - Relevant protection relays must be included in the model, explicitly where practically possible.
- Represent delays between *plant* elements (e.g. SCADA, PLC and park controller communication delays) that have an impact on the performance of the *plant*;
- Include adequate modelling of the mechanical components of the plant, to the extent that such mechanical components have a significant effect on the stability of the plant and its response to power system disturbances;
- Include models of *generating unit* or *bidirectional unit* energy storage components that would be affected by Disturbances;
- Represent plant response to any runback scheme or special protection scheme in which the plant participates in;
- Represent plant performance accurately within the normal dispatch range between minimum
 and maximum active power output, but must also be able to be initialised at any active
 power dispatch down to 0 megawatts (MW);

AEMO | [16 June 2023] Page 20 of 78

- Linearised models that are accurate only for a single operating point are not acceptable²⁷; and
- Can be initialised correctly (for example, for RMS models from load flow) if dispatched to a
 power level lower than that available from the fuel source.

Model multiple operating modes and control functions

A model must:

- Represent all modes of operation that the physical *plant* is capable of operating in. For example, if applicable to the physical *plant*, the model must be able to represent:
 - Generation, synchronous condensor and pump modes for relevant hydro-electric generation technologies, e.g. pumped storage.
 - Voltage control, power factor control and reactive power control modes.
 - Activation/deactivation of frequency control and fast frequency response features.

All automatic changes to operating modes that occur in reality should happen automatically within the model. Where automatic mode switchover cannot occur, operating mode changes must be based on configuration file or variable changes. It is not acceptable to require a separate model for each operating mode.

- Represent the simultaneous control functions that are active within the physical *plant* without the need to change model setup, variables or configuration parameters.
 - For example, a model must be able to represent both active power control and frequency control functions operating simultaneously.

Mid- and long-term dynamics

Any dynamic models provided for a *plant* must be adequate for simulation of the response of equipment, such as onload tap changer controllers, turbine governors, over-excitation or stator current limiters and any other thermal, *voltage* or *frequency* related controller with a time-delayed response up to 120 seconds.

Additionally, models must not change appreciably²⁸ during a flat-run (no Disturbance) simulation. Simulation durations for no-Disturbance studies range from 10 to 300 seconds (the latter to verify long-term Steady State stability).

4.3.2. Requirement for detailed load models

AEMO and the NSP may require more detailed load models, other than the IEEE ZIP load model or the Composite load models, under the following scenarios:

 The load needs to demonstrate compliance to relevant performance standards related to load transient performance following contingencies, or

AEMO | [16 June 2023] Page 21 of 78

²⁷ AEMO understands that this may be difficult to achieve for some plant with complex thermal componentry. Where the required accuracy cannot be met, AEMO will consider an application for an adjustment to this requirement in accordance with the Alternative Process detailed in Section 8.

²⁸ State changes in RMS models or noise/chatter in both RMS and EMT models are not expected to occur for flat-runs.

The load presents potential significant impact on power system operation, and the operation
of nearby generating systems, integrated resource systems and Network Users, subject to
the assessment of AEMO and the NSP as per the System Strength Impact Assessment
Guidelines.

Relevant model requirements in the following sections of Section 4.3 of these Guideline only apply to the detailed load models, and not to the IEEE ZIP load model or the Composite load models, unless specifically stated otherwise.

4.3.3. Requirements for Remedial Action Schemes

AEMO and the NSP may require Remedial Action Scheme (**RAS**) models where triggering of the scheme can lead to a material impact of the system. These models should encompass:

- Communication, measurement, filtering and processing delays (for example, intentional time delays like timer settings, or inherent delays like relay operating times).
- Calculation algorithms and logic/tripping sequences.
- Output actions including associated delays.
- Parameters, signals and status to be monitored.

Where possible, RAS models should be represented with standard objects from the relevant simulation software's model library²⁹.

4.3.4. Additional requirements for frequency stability studies

For frequency stability studies, models must also:

- Provide an accurate response of the plant to changes in network frequency, and active power supplied to or consumed from the network, regardless of whether it is enabled as FCAS:
- Take into account both central controllers and distributed plant if an aggregated service is used to provide FCAS;
- Be an accurate representation of the maximum rate of change of *frequencies* that the *plant* is capable of operating with;
 - For absolute changes in network frequency within the frequency operating standard
 where the plant is connected. If the performance standards of the plant exceed these
 limits, the models must be accurate for the full range of network frequency in which the
 plant can operate;
- Represent the frequency and speed filtering applied in the governor system controller and/or time delays in control variable measurement transducers;
- Represent any controller settable control variable position limits, ramp rate limits or deadbands;
- Include any mechanical actuator limits, for example, fuel valve open/close rate of change limits, pitch limits, open/close position limits, exhaust temperature limits, internal turbine

AEMO | [16 June 2023] Page 22 of 78

²⁹ Refer to the Remedial Action Scheme Guidelines

limits, active power limits or other physical limits within the *control system* that cause a limit on power output and/or fuel flow;

- Include fuel valves and fuel valve actuators that have control dynamics in addition to the
 control system, where these can affect the stability of the governing system or have an
 appreciable effect of the accuracy of the model must be included in the model;
- Include non-linear fuel flow to valve position and/or non-linear fuel flow to power characteristics, where an efficiency characteristic has an appreciable effect of the accuracy of the model;
- Include large Disturbance controls, such as intercept valve control on steam turbines, load rejection detection, acceleration control, power load unbalance detection and pre-emptive overspeed detection.
- Include external (to the governor/power control system) control action (e.g. from Generator
 or Integrated Resource Provider SCADA system), to regulate the power set-point during
 frequency Disturbances when enabled and not enabled for FCAS;
- Include control mode changes or control gain changes that may be triggered from network
 Disturbances (for example, in the case of islanding situations where the network frequency
 may vary within the normal contingency bands, or where special logic is used to boost FCAS
 capability);
- Represent any automated deployment of FCAS (specifically fast raise/lower and slow raise/lower service) where this is provided in addition to (or when a generating system or integrated resource system has been dispatched for a specified FCAS amount) or by normal governor action with additional algorithms or controls. Where other control logic is used (e.g. SCADA/AGC) to deploy the FCAS by direct control of the power set-point during a frequency Disturbance this must also be included in the model; and
- Represent the fuel delivery system dynamics where this has a material influence on the
 power output during and after a *frequency* Disturbance and within a timeframe up to five
 minutes from the initiating Disturbance, or where the fuel delivery system is common to
 multiple *production units*, or derived from the *generating system* or *integrated resource*system in other *production units* within a *plant* such that changes in *active power generation*on one *production unit* can cause a change on another *production unit*. Some examples of
 these are:
 - Hydro units being supplied from a common penstock/surge tank.
 - Combined cycle *plant* where a heat recovery system from gas turbines is used to generate steam for a steam unit.
 - Gas turbines where the turbine mechanical power decreases with frequency.

4.3.5. RMS model-specific requirements

The following are requirements for RMS dynamic models supplied to AEMO and the NSP:

Models must have a bandwidth of at least 0.05 hertz (Hz) to 10 Hz (for that part of the
response that is linear) and settle to the correct final value for the applicable power system
conditions and applied Disturbance(s);

AEMO | [16 June 2023] Page 23 of 78

- Models must initialise themselves in a Steady State consistent with the system conditions in
 the network load flow model. When these preconfigured system conditions are beyond plant
 operational limits or otherwise not consistent with valid operating conditions for the plant, the
 model must warn the user by way of a message to the progress output device;
- Where special tuning of the load flow case is required to replicate expected operating
 conditions with given control set-points, acceptability of the tuning procedure must be
 agreed to by AEMO and the NSP and documented in the RUG. Where a script is provided to
 assist with this procedure, it must be provided in the Python language;
- Changes to the Steady State operating point for the modelled element must not require
 changes to any external dynamic settings (for example, in PSS®E, CONs, and ICONs)
 except where the change cannot be adequately inferred from the network load flow case.
 Where the Steady State configuration of the model cannot be uniquely inferred from load
 flow (for example, Steady State wind speed when operating a wind turbine at 100% output),
 additional configuration parameters may be provided in runtime settable variables.
 Reasonable default values must be provided or inferred for any such parameters;
- When initialised at a valid Steady State operating point for the *plant* within operational limits, the model must correctly calculate state derivatives (for example, in PSS®E, models must not cause 'INITIAL CONDITIONS SUSPECT' messages at simulation start), unless there is a valid reason why this cannot occur (for example, the derivative of state of charge of a depleted battery initialised in charging mode). This will generally be the case when the derivative calculated for each state variable is no greater than 0.00001³⁰, or 0.01 times the initial value of the state variable (whichever is greater), in absolute value at time of initialisation:
- To avoid excessive simulation burden when integrating RMS models into Operations and Planning Data Management System (OPDMS) and dynamic security assessment (DSA) tools, the minimum permissible values of the numerical integration time step and acceleration factors are 1 millisecond (ms) and 0.2, respectively;
- Models must be compatible with dynamic simulation frequency dependency functions that the tool provides (for example, the Network Frequency Dependence option in PSS®E);
- RMS model outputs in terms of the voltage, frequency, active power and reactive power must be reasonably constant and consistent when doubling and halving the recommended time step;
- Models must be rigorously tested within a NEM-wide simulation for integration compatibility
 for large-scale power system studies. Experience has shown that single machine and infinite
 bus (SMIB) simulations do not always reveal new models' adverse interactions with other
 models in the system; and
- Models must not write messages to the console during a simulation run other than in response to error conditions to signal abnormal events (such as a protection trip) or when additional model-specific output has been requested by the user.

AEMO | [16 June 2023] Page 24 of 78

³⁰ PSS®E considers any state variable initialised with an absolute value less than 0.001 to be 'practically zero' and compares the calculated rate of change with the fixed threshold 0.01 for such variables. Otherwise, the ratio of the rate of change to the initial value is compared with the 0.01 threshold. In the worst case, an initial state equal to 0.001 will trigger a 'suspect' initial condition if its rate of change exceeds 0.00001.

4.3.6. EMT model-specific requirements

The following are requirements for EMT dynamic models supplied to AEMO and the NSP:

- Have a bandwidth of at least DC to 10 kHz and settle to the correct final value for the applicable power system conditions and applied Disturbance(s);
- Be based on *plant* design data and rigorously tested against factory acceptance tests for the corresponding version of *plant*;
- Include detailed representation of all inner and outer control loops for the plant³¹;
- Represent all electrical, mechanical and control features pertinent to the type of study being done³²:
- Have the full representation of switching algorithms of power electronic converters for power system harmonic studies;
- Have all pertinent protection systems modelled in detail for power system transient and
 voltage stability analysis, including balanced and unbalanced fault conditions, frequency and
 voltage Disturbances, and multiple fault conditions and can disable the protection systems if
 required;
- Be configured to match expected site-specific equipment settings;
- Allow plant capacity to be scaled;
- Transient stability EMT-type models must operate with a time-step greater than or equal to 1 microsecond, ideally consistent with the switching frequency of the *plant*;
- For EMT-type models used for harmonic analysis or real-time EMT simulations, time-steps
 must be such that they allow for an accurate representation of the switching algorithm of
 semiconducting devices;
- Allow model re-entry³³ to facilitate integration into larger system studies;
- Support multiple-run features to facilitate iterative studies;
- Allow multiple instances of the model within the same simulation;
- Be capable of self-initialisation, with initialisation to user defined terminal conditions within three seconds of simulation time:
- Warn the user by way of a message to the progress output device when the system
 conditions are beyond plant operational limits or otherwise not consistent with valid
 operating conditions for the plant; and

AEMO | [16 June 2023] Page 25 of 78

³¹ The model cannot use the same approximations classically used in transient stability modelling, and should fully represent all fast inner controls, as implemented in the real equipment. It is possible to create models which embed (and encrypt) the actual hardware code into an EMT component. This is the recommended type of model.

³² This may include external voltage controllers, plant level controllers, customized PLLs, ride-through controllers, SSCI damping controllers or others. Further details of required electrical and mechanical components are provided in Appendix C.

³³ This refers to the ability for a model to use the PSCAD™/EMTDC™ Snapshot feature, whereby the states and variables in an EMT model can be frozen in time and saved in a Snapshot file. The model can then be initialised in this state in subsequent simulations. For more information, please consult the "Initialization and Initial Conditions" section of the PSCAD™ online help system.

 Clearly identify the manufacturer's EMT model release version and the applicable corresponding hardware firmware version.

Multiple voltage disturbances

Where it is relevant to load models, the following modelling requirements for multiple voltage disturbance ride-through capability are applicable to user-defined site-specific EMT load models, for example where the load facility is expected to demonstrate compliance to relevant fault ride through capability performance standards.

The EMT model provided must account for the most restrictive³⁴ electrical, mechanical, or thermal protection of the *plant* with respect to multiple *voltage* Disturbances in quick succession, and calculate dynamically and accumulatively the impact of multiple *voltage* Disturbances, including but not limited to the following factors:

- Heat dissipation across the dynamic braking resistors (if applicable).
- Capability of auxiliary supplies, for example, uninterrupted power supply (UPS).
- Torsional stress protection on shaft drive train and prime mover (if applicable)³⁵.
- Protection associated with thermal design limits of the integral assembly of the plant.
- Any other relevant electrical, mechanical or thermal protection.

Note that these requirements apply only to EMT models as the simplifications of RMS plant models may result in inaccurate activation of fault ride-through mechanisms for unbalanced faults.

4.3.7. Accessible variables

Where applicable, all models must allow alteration to the following:

- All applicable set-points within all plant including (must be adjustable before and during a simulation run):
 - Active power
 - Reactive power
 - Voltage
 - Power factor
 - Frequency

For example, for a *generating system* or *integrated resource system* this infers access to all applicable set-points;

AEMO | [16 June 2023] Page 26 of 78

³⁴ It is the Applicant's responsibility to determine which protection element(s) will be the most limiting factor for multiple fault ridethrough.

³⁵ This is a relatively uncommon protection relay – the Generator must determine whether the exclusion of this relay from the model has a material impact on model accuracy.

- Deadband, droop, delays (including communication delays) and slow³⁶ outer loop controls for any applicable control system such as *frequency* and *voltage* control;
- · Ramp rates for changes in active power;
- Voltage and frequency protection settings, such as over/under voltage protection and over/under frequency protection;
- Fault ride-through activation and deactivation thresholds, including any multiple-fault ride-through limits and hysteresis levels;
- · Active and reactive current injection/absorption settings during a fault;
- Number of in-service generating units or bidirectional units and reactive support plant, adjustable before and during a simulation run; and
- Energy source input (for example, wind speed or irradiance), adjustable before and during a simulation run without causing any adverse impact on initialisation or dynamic performance.

Additional alterable variables may be required by AEMO or the NSP to undertake full stability impact assessment as described in the *system strength impact assessment guidelines*, for example, proportional and integral gains for inner/outer current/voltage control loops (including PLL, DC link current and voltage control, and any other control loops which can have a system strength impact). These variables can be adjusted by means of applying a real number multiplier if the actual values of these gains are preferred to remain black-boxed.

4.3.8. Model outputs

Table 5 outlines the output quantities required to demonstrate model performance for a variety of dynamic analysis scenarios. Quantities used to determine model accuracy are typically a sub-set of these quantities, and are described in Appendix D.

Table 5 Required model output quantities

Plant type	Plant internal quantities	Plant terminal measured quantities
Synchronous machines	Field current ^A Field voltage Limiter outputs ^B Mechanical power or torque Rotor angle Power System Stabiliser (PSS) output ^G Unit speed Automatic voltage regulator (AVR) output ^C Exciter output Valve position ^G Guide vane/needle positions ^G Governor control output ^G Set-point for active power ^G Set-point for voltage External protection relay(s) status ^H	Active power Total current ^E Frequency Reactive power Voltage magnitude ^E Voltage phase angle
Wind (generating unit)	DC link voltage and current Error/status codes ^D Generator rotor speed	

³⁶ Adequate for simulating actions of on-load tap changing transformers, static reactive plant switching, and 60 seconds Contingency FCAS.

AEMO | [16 June 2023] Page 27 of 78

Plant type	Plant internal quantities	Plant terminal measured
Flailt type	Flant internal quantities	quantities
	Active and reactive currents Mechanical torque or power Pitch angle Quantity determining FRT activation Set-point for active power Set-point for reactive power, voltage or power factor	
Photovoltaic (generating unit)	DC link voltage and current Error/status codes ^D Active and reactive currents Quantity determining FRT activation Set-point for active power Set-point for reactive power, voltage or power factor	
Battery (generating unit or bidirectional unit)	DC link voltage and current Energy storage level Error/status codes ^D Active and reactive currents Quantity determining FRT activation Set-point for active power Set-point for reactive power, voltage or power factor	
Traditional large load ^k	Largest direct-online (DOL) motor slip Largest DOL motor active and reactive power Largest DOL motor terminal voltage Protection relay(s) trip status ^H	
Inverter based load ^{K, L}	DC link voltage and current Energy storage level Active and reactive current FRT entry and exit status Controller setpoints Protection relay(s) trip status ^H	
HVDC link	DC link voltage and current Firing angle (for LCC HVDC) Switch / valve currents^A Error/status codes^D Active and reactive currents Quantity determining activation of blocking modes¹ Set-point for active power Set-point for reactive power, voltage or power factor External protection relay(s) status ^H	
Reactive compensation plant (such as static VAR compensators [SVCs], STATCOMs)	DC link voltage and current Shunt control status/set-points External plant set-point outputs Error/status codes ^D Active and reactive currents Quantity determining activation of blocking modes ^J Set-point for reactive power, voltage or power factor External protection relay(s) status ^H	
Centralised controllers (park and hybrid controllers)	Error/status codes ^D Quantity determining FRT activation Set-point for active power ^F Set-point for reactive power, voltage or power factor ^F	

AEMO | [16 June 2023] Page 28 of 78

Plant type	Plant internal quantities	Plant terminal measured quantities
	External protection relay(s) status ^H	

- A. In EMT models only.
- B. Relevant limiter outputs, such as over-excitation limiter, under-excitation limiter, V/Hz limiter etc.
- C. Including outputs of any compensation components.
- D. Only those error/status codes which translate into a distinct electrical system response at the low voltage (LV) terminals of the *plant*, for example, normal, fault, stop, low voltage ridr-through (LVRT) or high voltage ride-through (HVRT) activation, unstable mode identification.
- E. Both waveform and RMS values for EMT models.
- F. As sent to generating units or bidirectional units within the system.
- G. Not applicable for synchronous condensors.
- H. External discrete protection relays relevant to the *plant*. For example, for transient stability studies; this may include over- and undervoltage, over- and under-frequency, RoCoF and reverse-power protection. For black-start studies, this may be extended to include negative sequence, out-of-step, over-fluxing, loss-of-excitation and generator and unit-transformer differential protection.
- I. For line-commutated technologies, this would include the voltage-dependent current-order limit (VDCOL), and commutation failure (emulated in RMS models, simulated in EMT models). For both line-commutated and voltage-source technologies, blocking below certain *voltage* levels or other conditions should be modelled.
- J. Include within models the blocking response below certain voltage levels or other conditions.
- K.Only applicable to user-defined, site-specific load models, subject to the actual configuration of the load. For example, certain required quantities are not available when the according load component does not exist in the load facility, and does not need to be provided. L.The internal quantities are associated with embedded *generating units* or *bidirectional units* within the load facilities, for example, UPS within data centres, and hydrogen fuel cells within hydrogen protection facilities.

In addition to these internal and terminal quantities, models should provide access to the aggregated Reticulation Network and point-of-connection or unit transformer low voltage (LV) and high voltage (HV) to demonstrate the complete generating system or integrated resource system performance.

4.3.9. Integration compatibility

A model submitted to AEMO and the NSP for any *power system* element must operate as part of a full *power system* model alongside models of many other *power system* elements. This will inevitably include elements of the same type as the one in question, using either the same or a different release version of the same model code, submitted by the same or another *Registered Participant*.

It is, therefore, imperative that the model is capable of coexisting and operating correctly alongside other independent instances of the same model, either of the same version or with a different version number. This requires attention as a minimum to the following:

- Naming and referencing models, functions and libraries based on a version number, such
 that two different versions of a model of the same *plant* can run within the same simulation
 environment without interference;
- Creating models to work for a range of time steps and dynamic simulation parameters, rather than for specific settings only;
- Avoiding the use of global (FORTRAN COMMON) variables, including subroutine-level static (FORTRAN SAVE) variables, with persistent values, except where dynamic allocation is used to create instance-specific copies of such variables; and
- Models should, to the maximum extent practical, make use of the mechanisms provided within the host software platform to encapsulate separate model instances (for example, the pre-allocated STATEs and VARs in PSS®E).

Additionally, for EMT models, integration compatibility is improved by:

• Having all *plant* and *control system* models contained within a single EMT case, rather than spanning across a simulation set.

AEMO | [16 June 2023] Page 29 of 78

- Methods used to split a single *plant's* model components across several files for (typically SMIB) processing speed improvements may not be compatible with the broader case into which it will be integrated. Applicants must consult with AEMO and the NSP if simulation sets are required.
- · Having dependencies on a minimal number of external files.
- Model dependencies on external files having user-settable naming references.

Models that prove problematic to integrate into larger cases will need to be rectified before AEMO and the NSP are able to accept the model for further assessment. AEMO and the NSP will work with the Applicant to identify the issues.

4.3.10. RMS model source code

Source code of the RMS simulation model must be provided to AEMO, including all elements of the *plant* that affect its dynamic response, such as:

- For a generating system or integrated resource system, the unit model(s).
- Supervisory controls acting on the *plant* as a whole.
- Dynamic reactive support plant.
- Coordination of multiple reactive support devices and hybrid facilities.
- Any other *plant* such as *transformer* tap-changers whose response can reasonably impact the overall dynamic performance of the *generating system* or *integrated resource system*.

The model must be written and prepared using good model writing practices utilising the most recent model writing features and capabilities for the relevant software. For example, this would include the following:

- The models of the controllers and items of *plant* must be easily identifiable;
- The code should be commented to identify major components;
- Execution of dynamic data documentation commands should not result in model crashing;
- The model code should ensure correct implementation of windup and non-windup limits; and
- The model code should implement division and square root operations in a 'safe' manner to avoid division-by-zero and similar exceptions.

Additionally, for PSS®E RMS models:

- Using models which include calls into either of the CONEC or CONET subroutines is not
 acceptable. These calls can be avoided by adhering to 'table driven model' conventions in
 the model implementation. As of PSS®E version 34, table-driven models may be associated
 with most power system elements;
- Execution of the DOCU command should show all model states, outputs and constants that
 are observable/adjustable externally. The output format of these commands should be
 consistent with the format of dynamic data records;
- Using identical names should be avoided for models of similar structure where the number of one of the CONs, ICONs, VARs, or STATES is different between the two models; and
- The use of auxiliary or linking files is not acceptable.

AEMO | [16 June 2023] Page 30 of 78

4.3.11. RMS model format

RMS models submitted to AEMO for the purposes of load flow, fault analysis and conventional transient stability studies must be compatible with PSS®E version 34.7 or greater.

Provided an RMS model in an alternative format is readily available from original equipment manufacturers (**OEMs**), RMS models submitted to the connecting NSP must be compatible with the software package nominated by the NSP where an NSP uses a different RMS-type simulation tool, such as DIgSILENT Power Factory. RMS models should not have dependencies on additional external commercial software.

AEMO accepts RMS model source code natively developed in FORTRAN 90 or higher. FLECS code is no longer accepted.

4.3.12. EMT model format

EMT models provided to AEMO and the NSP must be compatible with PSCAD™/EMTDC™ version 5.0 and above and Intel Visual FORTRAN version 15 or higher. Models must not be dependent on a specific Intel Visual FORTRAN version or Visual Studio version to run. EMT models compiled in or requiring GNU FORTRAN or Compaq Visual FORTRAN to run will not be accepted.

EMT models that utilise any compiled or "blackboxed" code must follow the following criteria:

- Any compiled code must be provided in the format of a DLL in both 32 bits and 64 bits.
- The model including the DLL interface must not contain or utilise any static library files (for example, .obj, .lib).
- The interface must be in the form of source code (such as .f, .f90) and be compatible with both 32 and 64 bit compilers (separate interfaces for 32 and 64 bit is also acceptable).
- The interface must use explicit linking.
- The interface (and DLL) must be compatible with the PSCAD snapshot function.

AEMO's preferred approach for OEMs to achieve the above criteria is for DLLs to implement the Joint Working Group (JWG) B4.82/IEEE wrapper and provide an uncompiled (for example, .f, .f90) JWG B4.82/IEEE compatable interface.

EMT models should not have dependencies on additional external commercial software, however dependencies on free, commonly available redistributable libraries (such as E-TRAN) may be acceptable. AEMO will also accept DLLs that utilise redistributable libraries so long as the redistributable DLL file (for example, "msvcr100.dll") can be included with the model and successfully run without having to install the entire redistributable package.

Custom code blocks and electrical blocks are acceptable provided that they are implemented as a PSCAD Fortran script segment or an uncompiled Fortran file with no references to static library files and are compatible with the snapshot function.

4.4. Conventional EMT model requirements

Section 4.4 outlines the modelling requirements for conventional EMT studies that AEMO and the NSP may undertake outside of the *plant connection* process.

AEMO | [16 June 2023] Page 31 of 78

Models provided for these studies must comply with all EMT model requirements defined in Section 4.3, in addition the requirements below.

These requirements are not general requirements. They apply to relevant *plant* technologies only.

4.4.1. Black start model requirements

EMT models and simulations are required for adequately assessing the performance of *plant* and the *network* in black start scenarios. Models and Data Sheets for *plant* involved in *power system* restoration must be consistent with the high-frequency transient model³⁷ requirements of the tables within Appendix C, and include additional elements as follows:

Generator (Applicant provided):

- Major auxiliary loads including large fans and pumps greater than 1 MW each. The
 information provided should include the size and number of motors, their inertia, and
 operational reactances and time constants, and whether directly connected or interfaced via
 a variable speed drive.
 - Including details of the transformers that supply the auxiliary loads.
- Descriptions of any special abilities of the plant (for example, soft-start capable, TTHL bypass valves).
- A detailed description of any special control schemes active during system black (for example, changes to governor PID controllers while in isochronous mode).
- Surge arrester manufacturer, types, and V-I profiles.

Network (NSP provided):

- Geometrical representation of transmission lines, including conductor type and associated resistance, cable bundling configuration, transpositions (for lines above 5 km), tower types and spacing.
- *Transmission network transformers*, including saturation profile, air core reactance, winding configurations, number of limbs, all reactances and time constants.
- X and Y *transformer* differential protection relays, with on-site settings.
- Locations of synchronising breakers and synchrocheck relay settings.
- Details of under- or over-voltage protection schemes active in key network corridors.
- Surge arrester manufacturer, types, and V-I profiles.

Reactive support plant (NSP provided):

- Full representation of the reactive support *plant* and all *control* systems.
- Step-up *transformers*, including saturation profile, air core reactance, winding configurations, number of limbs, all reactances and time constants.
- All relevant X and Y protection relays with on-site settings.

AEMO | [16 June 2023] Page 32 of 78

³⁷ These models must represent fast- and slow-front transients as defined by the IEC Standard 60071 Part 1.

- A detailed description of any special control schemes relevant during system restoration (for example, gain reduction for static VAR compensators [SVCs]).
- Surge arrester manufacturer, types, and V-I profiles.

Large single load models are not required from *Network Users*, unless the *Network Users* intend to participate in the restoration process, or intend to provide system restoration services.

4.4.2. Sub-synchronous model requirements

These studies are specialised and are not conducted routinely. If AEMO and the NSP determine that such studies are required to support secure system operation, adequate EMT models must be made available by the asset owners to facilitate the studies. Models provided for these studies must comply with all EMT model requirements defined in Section 5.4, in addition the requirements below.

Sub-synchronous resonance (SSR)

In addition to standard *generation* model components, owners of conventional synchronous generators may be required by AEMO and the relevant NSP to model the turbine-generator mechanical system as a lumped-mass model if it is determined that SSR studies are required for the *plant* under consideration.

The lumped-mass model consists of multiple masses representing different turbine shaft sections with each individual mass defined by its portion of mechanical torques, inertia constants, torsional stiffness between adjacent masses, and damping coefficient associated with each mass³⁸.

Models used for such studies can be confirmed through a combination of:

- Factory acceptance testing of the turbine-generator mechanical system.
- Using measured generator terminal quantities and performing a discrete or fast Fourier transform to confirm the frequencies of the torsional modes, which is then compared against the calculated torsional mode frequencies using inertial constants and stiffness. This applies to existing synchronous generating systems only.

Sub-synchronous control interaction (SSCI)/sub-synchronous torsional interaction (SSTI)

The level of detail required for these studies are provided under the "sub-synchronous interaction" entries of tables in Appendix C.

4.4.3. Format

EMT models for conventional EMT study purposes must be submitted in the format specified in Section 4.3.12.

4.5. Small-signal model requirements

Small-signal stability models are required for *plant* that contribute to local, intra-regional and inter-regional frequency modes in the *power system*. This includes synchronous *generators* and

AEMO | [16 June 2023] Page 33 of 78

³⁸ Information on damping coefficient is typically difficult to acquire, and is a function of the turbine-generator output. Information on inertia constants, torsional stiffness between adjacent masses and the portion of mechanical torque attributed to each mass must be provided.

their power oscillation dampers (**POD**s), dynamic reactive support plant with PODs, and any other *plant* which can reasonably impact damping of small-signal oscillations as determined by AEMO and the relevant NSP.

Small-signal stability models may also be required for studying the effects of sub-synchronous oscillations, such as inverter control system interactions up to 25 Hz. This will include any *plant* which can potentially contribute to such oscillations as determined by AEMO and the relevant NSP.

For synchronous machines, a fully validated RMS transient stability model is generally sufficient for this analysis, provided that the corresponding small-signal model can be derived from block diagrams or source code using standard mathematical linearisation techniques.

For asynchronous technology, small-signal models derived from RMS transient stability models may be inadequate in studying such phenomena. AEMO suggests that small signal models represent all sub-synchronous frequencies.

4.5.1. Format

Small-signal stability models are submitted as part of the model package. This is to be in the form of block diagrams, a Small Signal Analysis Toolbox (**SSAT**) model, frequency response data, or some other format. The format is to be determined through discussion between AEMO, NSPs, *Registered Participants* and OEMs.

SSAT is the currently nominated small signal modelling tool. Models submitted in this format must be compatible with SSAT version 22 or greater.

4.6. Power quality model requirements

The following sets out the requirements for power quality models.

4.6.1. Harmonic emissions

Harmonic current injection models used for harmonic frequency scans and harmonic distortion analysis in conventional *power system* harmonic analysis tools must provide:

- Frequency-dependent Norton equivalences of each type of generating unit or bidirectional unit;
- Harmonic current injection profiles (for each harmonic order) at each *generating unit* or *bidirectional unit*, including:
 - Harmonic current magnitude, for example, in Amperes, or in percentage of fundamental current;
 - Harmonic current phase angle (only if the harmonic emission calculation method advised by the relevant NSP requires this information);
- Adequate model of collector grid³⁹;

AEMO | [16 June 2023] Page 34 of 78

³⁹ Collector conductor models may need to consider skin and conductor proximity effects.

- Generating unit or bidirectional unit transformer models and generating system or integrated resource system transformer models⁴⁰;
- Data for harmonic filters (if present), including connection point(s) of the filters, filter layout (for example, single-tuned, double-tuned), qualify factor and electrical parameters; and
- Where EMT-type models are used for harmonic analysis the requirements set out in Section 4.3.12 will apply⁴¹.

The origin and methodology of the Norton equivalent sources must be documented and provided. Where harmonic current injections sources are provided in the form of harmonic current magnitude only, a method needs to be applied to summate the effects of the many individual harmonic sources in the *plant*.

A common method that has been used is the IEC Second Summation Law, as defined in IEC TR 61000.3.6-2012. From one of the findings documented in CIGRE Technical Brochure 672, "Power quality aspects of solar power", the standard summation exponents are not suitable to be used.

For photovoltaic *generation* using multiple inverters of the same manufacturer, harmonic currents should be added arithmetically independent of the harmonic order. Currently, no such finding has been published for wind *generation*, however, until different findings for wind *generation* are published, the same approach of applying arithmetically sum can be adopted for wind *generation*.

Format

Harmonic models must be provided in a format that is compatible with the harmonic analysis software platform nominated by the relevant NSP. This can be divided into types of simulation tools:

- Conventional harmonic simulation tools based on current injection techniques.
- EMT-type simulation tools where all requirements specified above will remain valid.

Depending on the specifics of the *connection point* and proximity to other sources of harmonics, both types of simulation models may be needed for a given *connection*.

4.6.2. Harmonic susceptibility and resonances

To account for the harmonic signature of asynchronous plant in harmonic susceptibility and resonance studies, it is necessary to include appropriate harmonic models of the harmonic generating devices, the harmonic impedance profile of the *network*, and the *frequency* dependent behaviour of the *network* elements. Where EMT harmonic susceptibility and resonance studies are required, model components as outlined within Appendix C for harmonic studies must be included.

AEMO | [16 June 2023] Page 35 of 78

⁴⁰ Positive, negative and zero sequence impedance of these *transformer* models must be provided, including any earthing arrangement and *transformer* vector groups.

⁴¹ This is not a general requirement and will be determined on a case-by-case basis and only when the conventional harmonic analysis techniques fail to achieve the required level of accuracy.

Format

Models used for harmonic susceptibility and resonant analysis must be provided as an EMT model complying with the format requirements of Section 4.3.12. The EMT model must comprise all control systems and switching components that contribute to the *plant's* harmonic profile. Further details of required components are provided in the "Harmonics" entries of the tables in Appendix C.

4.6.3. Flicker

The simulated RMS *voltage* magnitude/voltage waveform obtained from either RMS or EMT time-domain simulation can be fed into a flicker meter model following IEC 61000-4-15 for assessing the short-term and long-term flicker severity. These time-domain models are expected to include adequate representation of characteristics/functions/control systems involving/causing flicker.

Format

Models must comply with the RMS and EMT format requirements of Section 4.3.11 and Section 4.3.12.

4.6.4. Voltage unbalance

Models provided for harmonic studies are sufficient for *voltage* unbalance studies from a *generator* source perspective, however *network* elements that adequately represent *voltage* unbalance must also be included.

Models used to investigate this phenomenon must include the following:

- Steady state 50 Hz negative-sequence current injection, both magnitude and phase angle (phase angle is relative to the 50 Hz positive-sequence current phase angle), from the devices connected at the assessed bus must be modelled.
- Transmission lines must be modelled in the form that the information of 50 Hz negativesequence impedance and the coupling impedance linking 50 Hz negative-sequence voltage and 50 Hz positive-sequence current are captured (for example, geometrical line representation).
- Negative-sequence impedances for synchronous machines and loads must be modelled.
- A variation of different power flow scenarios as well as other Steady State 50 Hz negativesequence current injection devices must be modelled to capture the variations of the background network 50 Hz negative-sequence voltage contribution.

Additionally, known *voltage* unbalance susceptibility within the *plant* must be represented within the *voltage* unbalance model and provided within documentation.

Format

Models for voltage unbalance studies must be compatible with:

- The EMT model format requirements specified in Section 4.3.12; or
- A suitable power quality analysis tool as nominated by the relevant NSP.

AEMO | [16 June 2023] Page 36 of 78

4.7. Model aggregation

Traditionally there has been a one-to-one correspondence between *power system* elements such as *generating units* and the models of these elements in simulation software. Thus, each *generating unit* has been represented individually in the *power system* model. This is practical when the *power system plant* is a large *power station* comprising up to about a dozen individual large *generating units*.

However, contemporary *generating systems* or *integrated resource systems* such as wind and photovoltaic solar farms, as well as other *plant* such as grid-scale battery installations, can include as many as several hundred *production units*. As these *production units* are usually identical to one another, this has the effect of multiplying the required computational effort and simulation run time for little benefit, compared to representing these identical *production units* as a smaller number of aggregates.

For such systems comprising of scores of small *production units*, the general rule is that the submitted *plant* model should contain no more than four *production units* of any one type. That is, *production units* should be combined into aggregates with each aggregate representing multiple individual *production units*. In the simplest cases, a single aggregate may suffice to represent the totality of *production units*.

Aggregation should not be used to combine *power system* elements of differing types. These should retain separate explicit model representations, albeit some may be aggregates of identical *production units* of that same type. An exception may be made where elements are similar in all material respects other than size (for example a 3.0 MW and a 3.2 MW wind turbine with the same underlying technology and control systems) and where evidence is provided of this similarity by way of manufacturer documentation, to the satisfaction of the NSP and AEMO.

A similar aggregation principle can be applied to large inverter-based loads (**IBL**s) consisting of small, identical modular components, such as a hydrogen production facilities consisting of multiple electrolyser clusters.

The largest DOL inductor motor within a single load facility should be modelled explicitly, for loads where a model is assessed to be required. Other smaller motors can be modelled as lumped motors, provided the size of any lumped motor is smaller than the large inductor motor on site.

4.7.1. Scaling principles for derivation of multiple-unit aggregates

The following general principles are assumed as the default for producing aggregates of N identical *production units*, where each *production unit* is assumed to consist of a 'plant' at low voltage (LV) in cascade with a unit transformer stepping up to medium voltage (MV).

The MV 'collector system' which connects the individual *production units* together is treated separately in Section 4.7.2.

Where the modelling of *power system plant* requires an aggregation method that varies from these principles, this must be clearly documented in the RUG. Alternative aggregation methods include the provision of a separate aggregate model not directly derived from the individual *production unit* model. Evidence must be submitted to AEMO and the relevant NSP for the suitability of the aggregation method relative to the simple application of the scaling principles below. AEMO and the NSP must jointly assess this evidence, and may accept the different method, or determine that the scaling principles will apply if the evidence submitted is weak.

AEMO | [16 June 2023] Page 37 of 78

- The aggregate *production unit* is represented in the model in an analogous fashion (size aside) to a single *production unit*. It has the same associated dynamic model and appears similar to a *unit* in the *network* model in cascade with an equivalent unit *transformer*.
- The LV and MV voltage levels are the same for the aggregate as for the individual production units.
- The megavolt amperes (**MVA**) rating of the aggregate *plant* is N times the MVA rating for an individual *production unit*. (This rating is called MBASE in the PSS®E software.)
- The active power and reactive power of the aggregate are the sums of the individual production unit powers. For modelling purposes, there is an underlying methodological assumption that each production unit has identical power outputs, although these will vary from unit to unit.
- Any other 'size quantities' specified in SI units, or in per-unit on a fixed system MVA base, are multiplied by N in the aggregate. Examples of size quantities are rated current in Amperes, rated torque in Newton-metres, and inertia constant in Joules or VA-seconds (but not speed or voltage). Where, on the other hand, the model specifies these quantities in a per-unit system on the production unit MVA base, their numerical values are identical.
- The MVA rating of the aggregate *unit transformer* is N times the MVA rating of each *unit transformer*.
- Any internal series impedances of the aggregate production unit, unit transformer and any
 intervening LV cables, when specified in ohms or in per-unit on a fixed system MVA base,
 have values 1/N times their values for each corresponding production unit. Where, on the
 other hand, the model specifies these quantities in per-unit on the production unit MVA
 base, their numerical values are identical.
- Any internal shunt admittances of the aggregate production unit, unit transformer and LV cables, when specified in Siemens or in per-unit on a fixed system MVA base, have values N times their values for each corresponding production unit. Where, on the other hand, the model specifies these quantities in per-unit on the production unit MVA base, their numerical values are identical.

Implicit in these scaling principles is a requirement that the underlying model of the *production unit* is also capable of representing the aggregate of N *production units* when configured with the larger MVA rating. If appropriate, the model may be coded to indicate the level of aggregation explicitly in the model configuration (for example, by including either each *production unit* size or the number N of identical *production units* as a configuration parameter). However, any necessary change to model configuration or settings beyond those stated above when switching between an individual *production unit* and aggregate representation, or between aggregate representations with different numbers of *production units*, must be clearly documented in the RUG.

4.7.2. Representation of collector systems in aggregated models

Special attention must be given to the aggregated representation of the MV 'collector system' that connects the MV terminals of the *unit transformers* and (usually) conveys the aggregate *generated* or consumed power to an MV *collector bus* at the relevant substation.

In the simplest case, all identical *production units* are combined into a single aggregate, and the model specifies a single equivalent collector impedance connected between the MV collector

AEMO | [16 June 2023] Page 38 of 78

bus and the MV terminal of the aggregate equivalent *unit transformer*. In this case, the recommended procedure for calculating the equivalent collector impedance is given in National Renewable Energy Laboratory (**NREL**) report NREL/CP-500-42886, "Method of Equivalencing for a Large Wind Power Plant with Multiple Turbine Representation"⁴². This procedure is based on calculating the equivalent series resistance and reactance that yield the same *active power* and *reactive power* consumption as the original MV collector system, where the *production units* in that system are assumed for simplicity to all operate at identical *voltage*.

The same procedure must be applied when the system is divisible into up to four component subsystems, each with its own independent *connection* to an MV collector bus. In this case, each subsystem furnishes its own aggregate with the equivalent collector impedance calculated as above.

The Applicant may propose an alternative aggregation method to the NSP and AEMO, who will jointly assess it. An alternative method is required in any case where the *plant* layout does not readily fit in either of the two categories above. As a matter of principle, it is noted that there is no one correct way to aggregate any collector system, and different principles such as equalising losses (as per Muljadi et al), or reproducing an equivalent MV *voltage* diversity, will yield different results. All aggregation methods implicitly induce a degree of modelling error which must be acknowledged whenever comparisons are undertaken between modelled and true *plant* behaviour.

4.7.3. General considerations

For a *generating system* or *integrated resource system* with many *generating units* or *bidirectional units*, provision of the required aggregate model will be the primary method considered for wider *power system* studies and for AEMO's own assessment tools.

Aggregate models should continue to provide access to the LV terminal bus quantities for each aggregate equivalent *production unit*, including *active power*, *reactive power* and *voltage* magnitude. This includes EMT models that have been black-boxed. Figure 2 shows a high-level example of how an EMT model that has been aggregated and black-boxed can provide access to terminal quantities.

Figure 2 Aggregated and black-boxed EMT model high level representation

For model validation purposes, the aggregated *production unit* and aggregated *system* responses must conform to the accuracy requirements in Section 6.2, where the individual aggregated *production unit* model terminal quantities have a slightly moderated accuracy tolerance compared to the model *connection point* quantities. The procedure for R2 validation will involve collecting field measurements both for the aggregate *system* and for one representative *production unit* for validation.

High voltage plant connecting directly to the transmission network is to be explicitly modelled.

4.8. Model and plant updates

While each submitted model must be a faithful representation of the *plant* at the time of submission, it is natural to expect that updates to the model will be issued from time to time by the supplier or other party responsible for the model.

It is especially important that alterations to the *plant* or its control firmware that alter the *plant's* dynamic performance are correctly reflected in an updated simulation model. It is also possible for several reasons for model updates to be proposed without any change to the *plant*.

4.8.1. Updates to account for simulation model improvements

The reasons for model updates relating to simulation improvements include the following:

- Updates to improve computational or numerical performance of the model code.
- Updates to incorporate additional functionality provided with newer versions of the same equipment, or to allow greater flexibility in configuration.
- Updates to broaden the scope of the model code to represent multiple equipment types within the one family, by varying the configuration parameters.
- Updates to correct 'bugs' or unanticipated performance issues, particularly to reflect novel 'use cases' arising during long term operation.

In general, an update to a model held by AEMO and the NSP for specific *power system plant*, in the absence of any alteration to the *plant* itself, will be considered only where it is relevant to

AEMO | [16 June 2023] Page 40 of 78

the performance of that element in ongoing dynamic assessments (including the performance of the simulation software itself). Where the update is relevant only to accommodating future *plant* using the same model, it is generally expected that the existing *plant* will continue to use the 'old' model, which will continue to perform adequately after new *plant* are introduced using the updated model version.

The updated model's acceptance by AEMO and the relevant NSP will be subject to additional dynamic model acceptance testing conducted by AEMO or the NSP at the Applicant's expense.

4.8.2. Updates to account for changes in the plant including parameter changes

Updates to *plant* firmware or settings that alters dynamic performance or protection operation must be captured in a revised dynamic model(s) to be submitted to AEMO and the NSP. The revised dynamic model(s) must be accompanied by a report that shows the revised model(s) and its settings meets all accuracy requirements to 'R1'⁴³ level, prior to acceptance of *performance standards* for the altered *plant*⁴⁴. This will be followed by on-system tests as part of *plant* commissioning, including tests to validate the revised dynamic model(s) to R2 level.

The updated model's acceptance by AEMO and the NSP will be subject to additional dynamic model acceptance testing conducted by AEMO or the NSP at the Applicant's expense.

4.8.3. Updates to account for later versions of simulation tools

Occasionally⁴⁵, it may be necessary for AEMO and the NSP to move to later versions of RMS and EMT simulation tools. Ideally, later versions of these simulation tools will be backwards-compatible with existing models, or where AEMO has the source code for RMS models, AEMO will independently recompile the model and update model libraries.

However, if AEMO or the NSP deem it necessary that a later version of a simulation tool is required to undertake studies, and an Applicant's existing model no longer functions correctly in the later version of the simulation tool, an update to the Applicant's model is required to provide compatibility with the later version of simulation tool. This model update is required from the Applicant without cost to AEMO or the NSP. These updates may be required at any point in the life of the *plant*.

4.8.4. Updates to account for additions to otherwise unaltered legacy plant behind a connection point

During the lifetime of an *generating system*, *integrated resource system*, or customer installation established under superseded modelling requirements, augmentations may be undertaken by the *Registered Participant* that have the effect of adding equipment behind the existing connection point but otherwise leaving the established system unaltered. Up-to-date models are then required for both the new and the legacy plant, having regard to balancing the

AEMO | [16 June 2023] Page 41 of 78

⁴³ 'R1' refers to pre-connection in the sense that it is used in NER S5.5.6.

⁴⁴ See NER 5.3.10 for *Generators* and *Integrated Resource Providers*. NSPs have a general obligation to ensure that modelling data used for planning, design and operational purposes is complete and accurate at all times and provide it to AEMO and other NSPs if reasonably required to model the static and *dynamic performance* of the *power system* (see NER 5.2.3(d)(8) & (9)). MNSPs and *Customers* cannot *connect* altered equipment until an *application to connect* is made and a *connection agreement* is entered into (see NER 5.2.3(g) and 5.2.4(b), respectively).

⁴⁵ For example, between 2009 and 2023, AEMO has needed to change PSS®E versions twice: v29 to v32, and v32 to v34, and PSCAD™ versions twice: v4.2 to v4.6 and v4.6 to v5.0.

following principles on a case-by-case basis, in accordance with Section 8.3 and 8.4 of the Guidelines:

- Models for the new plant must be provided in accordance with the current Guidelines, as per current good industry practice.
- To the extent that the legacy plant and the new plant are likely to interact in a manner material for system stability and security, models for the legacy plant should be provided in accordance with the current Guidelines to the extent reasonably practicable.
- The requirement for updated model provision must not act as a material disincentive to Generators, Integrated Resource Providers and Network Users undertaking augmentation works that are likely to be of benefit to the NEM.

From a technical modelling perspective, industry experience suggests that material interactions between legacy and new plant in the system are most likely to arise from one of the following four components:

- Outer control loops for voltage and/or reactive power within a plant.
- Inner control loops driving unit-level voltage and current, including fault ride-through modes and PLL dynamics for electronic equipment.
- Outer control loops for dispatch and regulation of active power production or consumption by the plant.
- Outer control loops for frequency responses and control.

For example, generic models can be used to represent legacy plant when detailed site-specific models cannot be obtained to the best of proponent's effort. The generic model should include all information related to the components listed above. Components which can be validated as per the R2 validation process must be included in the legacy plant generic models, where practical.

Other components of the generic model, which cannot be validated during the R2 validation process, can be validated by the proponent through the ongoing compliance monitoring scheme, and the validated model should be provided to AEMO and NSPs within a time frame to be agreed with AEMO and NSPs.

Consideration will also be given to the availability within the NEM of models for similar equipment which might be adapted to the legacy plant through parameter reconfiguration.

5. Model documentation

Information required for the modelling of *power system plant* for all applicable studies including load flow and fault level studies, specialised studies, black-start studies, power quality analysis, connection assessments, stability assessments and *system strength impact assessments* is required in a number of forms. For example:

- The RUG, required under NER S5.2.4(b)(8), for both RMS and EMT models⁴⁶;
- Completed Data Sheets, required under NER S5.2.4(a);

AEMO | [16 June 2023] Page 42 of 78

⁴⁶ Where the requirement to provide a RUG arises by virtue of the application of NER S5.5.7(b1)(1)(i), the requirement applies to all *generation*, not just *generation* with a nameplate rating of ≥ 30 MW.

- Functional block diagram information for RMS models, required under NER S5.2.4(b)(5);
 and
- Model source code information for RMS models, required under NER S5.2.4(b)(6).

This model information must be consistent. For example:

- The specific parameters relevant to a dynamic model required in tabular form by the Data Sheets, must be found in the functional block diagrams, also required by the Data Sheets⁴⁷;
- The functional block diagrams for RMS models required by the Data Sheets, must match the functional block diagrams provided under NER S5.2.4(b)(5); and
- The functional block diagrams for RMS models provided under NER S5.2.4(b)(5) must match model source code information provided under NER S5.2.4(b)(6).

5.1. Releasable user guide

The RUG accompanies a model to describe how it is to be used and includes other information such as *transformer* modelling information, operational information, information on *protection* systems or *control systems* that are relevant to the assessment of proposed *performance* standards, and *connection point* information. This information in a consolidated form is required to facilitate the *connection* and other studies and to avoid misinterpretation and potential errors.

The RUG is routinely sent to *Registered Participants* as required by the NER, and as such, should not contain any information that is considered confidential. The RUG must be written such that a *Registered Participant*, without any prior knowledge of the *plant*, would be able to successfully perform studies.

RUGs should comply with the template set out in the Guideline for Preparation of a Releasable User Guide⁴⁸.

5.2. RMS and EMT model documentation

Supporting documentation included in the RUG must be relevant to the site-specific model and must contain sufficient information for AEMO and the NSP to use the RMS and EMT models to carry out due diligence and *power system* studies.

The information in the supporting model documentation includes:

- Information that is necessary to allow modelling of the plant (in the case of generation, both
 each generating unit and generating system) for connection assessment and other power
 system studies;
- Instructions on the use and operation of the RMS and EMT models, including operational limitations:

AEMO | [16 June 2023] Page 43 of 78

⁴⁷ The identical numerical value may not match between the parameter requested in the table and the functional block diagram due to differences in *production units*, or a requirement to provide parameter information in a functional block diagram in 'per unit' form, however, it is expected that the parameter is recognisable in the functional block diagram.

⁴⁸ Available at: http://www.aemo.com.au/~/media/Files/Electricity/NEM/Network Connections/Transmission-and-Distribution/Guideline-and-Template-for-preparation-of-a-Releasable-User-Guide

- Descriptions and setting values for control sequences (for example, fault ride-through control schemes and any other relevant *control systems*) that are relevant to the intended use of the model;
- Descriptions, site-specific values and ranges of all configuration parameters, component trip/status codes used in the RMS and EMT models; and
- Descriptions, site-specific values and ranges of all user-adjustable variables and *control* system settings contained within the model.

5.2.1. Additional information required for fault level calculations

Additionally, plant using converter-connected technologies must:

- State within the RUG timeframes which short circuit related parameters of the supplied model are appropriate; and
- Provide information on the magnitudes and phase angles of the phase-current connection
 point contributions that their equipment is expected to make (as a function of connection
 point voltage-dip magnitude and duration) for the following types of voltage dips:
 - In only one phase;
 - Equal dips in two phases and none in the third; and
 - Equal dips in three phases.

5.2.2. RMS model block diagrams

Block diagrams must be submitted alongside all RMS models. Several attributes will be assessed:

- The transfer function block diagram must include all functional controllers and *plant* that materially affects the performance of the model⁴⁹.
 - The models of the controllers and items of *plant* must be easily identifiable.
 - All individual blocks should be expressed explicitly. The use of black-box type approach for representing any of the individual transfer function blocks is not acceptable.
 - The interconnection of the different functional controllers and the items of *plant* must be clearly shown.
- Images and tables embedded in documents must be of sufficient resolution to easily identify all components, parameters and values.
- The transfer function block diagram must be described by Laplacian (preferred) or Z-domain transfer functions.
- The transfer function blocks and model parameters must be recognisable in terms of the
 physical design of the plant and control system settings, to allow the NSP or AEMO to
 assess control system settings proposed by the Applicant, or design new settings.
- The transfer function blocks and model parameters must include any relevant non-linearities, such as limits, arithmetic or mathematical functions, deadbands or

AEMO | [16 June 2023] Page 44 of 78

⁴⁹ Included in this category are the central park level controllers that schedule active and reactive power across wind and photovoltaic solar farms.

saturation. Any limits must be shown as windup or non-windup limits. Non-windup limits must show how the non-windup nature of the limit is achieved (for example, which model state variable is being limited and the relationship between the limit value and the state variable that is being affected by that limit).

- The model parameter values must reflect typical values appropriate for the actual equipment installed. All model parameters and their values must be shown either directly in the transfer function block diagram or in a tabular format.
- Control systems with several discrete states or logic elements may be provided in flowchart format if a block diagram format is not suitable.
- Parameter values that are intended to be (or can be) externally adjusted (for example, those
 explicitly in PSS®E dynamic data file, VARs, CONs, ICONs) must be clearly identified in the
 model block diagram.
- The model block diagram and flowcharts (if applicable) must represent the corresponding model source code⁵⁰.
- The model inputs and outputs shown in the transfer function block diagram representation should match those indicated in the Data Sheets.
- The state variables shown in the transfer function block diagram representation should match those indicated in the Data Sheets.
- Model documentation and transfer function block diagram representation should be provided at the level of detail required for AEMO and NSPs to derive the corresponding linear smallsignal model of the equipment.
- Dynamic data must be provided as 'per unit' quantities on the machine MVA base⁵¹.

5.3. Small-signal stability model documentation

Supporting documentation for small-signal stability models will depend on the format that the model is submitted as set out in Section 4.5. Content of small-signal stability model documentation should be developed through discussion with AEMO, NSPs, *Registered Participants* and OEMs.

5.4. Harmonic model documentation

Harmonic model documentation must be sufficient for the relevant NSP to understand and use the harmonic model in the software package of their choice. Where the harmonic model provided is an EMT model, the principles set out in Section 5.2 should be adhered to when developing documentation, with specific differences between the harmonic and transient stability EMT model highlighted.

Additionally, documentation for the harmonic model must include any or all of the following as agreed with the relevant NSP and AEMO on a case-by-case basis:

AEMO | [16 June 2023] Page 45 of 78

⁵⁰ It is also expected that the functional block diagrams provided with the Data Sheets for a *generating system* will match these diagrams, although the parameter values might differ to reflect *connection point* performance requirements.

⁵¹ If another base is more practical, such as the turbine-governor quantities based on the turbine MW rating, this may be acceptable as long as it is clearly identified as such in the model and documentation.

· Harmonic emission studies:

- A harmonic profile at different loading levels, between 0 to 100%, in 10% steps if it is demonstrated the harmonic current profile varies linearly as function of the loading;
- A suitable frequency-dependent Norton equivalent for the harmonic injecting device to clearly demonstrate how the current injected and the equivalent impedance vary as function of harmonic order: and/or
- Documents describing the suitability of the EMT-type model submitted consistent the level of modelling discussed in Appendix C.
- Harmonic susceptibility studies:
 - Documents describing the suitability of the EMT-type model submitted consistent the level of modelling discussed in Appendix C.

6. Model accuracy requirements

This section specifies model accuracy requirements. These model accuracy requirements:

- Are applicable regardless of the type of model provided;
- Will apply regardless of the type of generating system, integrated resource system and plant, and
- Will apply to detailed IBL models other than IEEE ZIP and Composite load models.

6.1. Accuracy locations

Model accuracy must be demonstrated for all components within a *plant* that impact on *power system* dynamic performance.

Synchronous plant typically requires demonstration of model accuracy at each *generating units*' terminals.

Power electronic interfaced asynchronous technologies (such as wind and photovoltaic solar generating systems) may consist of several generating or bidirectional units, plant controllers, Reticulation Networks and dynamic reactive support devices such as STATCOMs and synchronous condensors. As such, demonstration of model accuracy must occur at:

- Connection point or high voltage terminals of plant transformers.
- Reticulation Network collector bus to which an individual item of dynamic plant is connected.
- Generating or bidirectional units (for each different type of production unit, including batteries).
- Terminals of each type of dynamic reactive support device, such as STATCOMs and synchronous condensors (if applicable).
- Central park-level controllers, and any other overarching coordinated controllers.

Demonstration of model accuracy for IBL models must occur at the connection point or high voltage terminal of the main supply transformer.

AEMO | [16 June 2023] Page 46 of 78

6.2. Model performance measures

The performance measures described in Section 6.2 must be used to determine the model accuracy, where all accuracy bands are to be referenced to the model's response. A table specifying quantities to which these requirements apply is provided in Appendix D.

General considerations are:

- The term "transient window" is used to describe the moment a reference change or
 Disturbance commences until the response returns to within ±5% of the model's maximum
 induced or reference quantity change. Appendix E provides a visual representation of this
 definition.
- Accuracy of EMT model responses are evaluated on their simulation-tool calculated RMS quantities⁵², with filtering appropriate for a 50 Hz nominal system. Larger filtering time constants on measurements will require justification.

6.2.1. Accuracy criteria

The following criteria apply, and no criterion should override another, except where noted:

- (a) For synchronous plant control system models, the overall linear response over a frequency bandwidth of at least 0.1-5 Hz must be within the following tolerances:
 - (i) Magnitude must be within 10% of the actual *control system* magnitude at any frequency; and
 - (ii) Phase must be within 5 degrees of the actual *control system* phase at any frequency.
- (b) For time domain responses that include non-linear responses or performance, as well as responses to switching or controlled sequence events (for example, operation of fault ride-through schemes and converter mode changes), the key features of the response are within the following tolerances:
 - (i) Rapid slopes in the actual *plant* response, compared with the simulated response must be within the less restrictive of:
 - (A) ±10% of the change for 95% of the samples within the transient window; and
 - (B) From the start to the finish of the slope, a difference of less than 20 ms.
 - (ii) For rapid events caused by control sequences (such as some fault ride-through control schemes) or switching events, the sizes of peaks and troughs (measured over the total change for that peak or trough) must be within 10% of the change for 95% of the samples within the transient window;
 - (iii) Oscillations in the actual response of the *plant* for *active power*, *reactive power* and *voltage* in the *frequency* range 0.1 to 5 Hz must have damping⁵³ and *frequency* of the oscillation within 10% of the simulated response for 95% of the samples within the transient window. The phase angle between different quantities (e.g. *active power* versus *reactive power*) at the oscillation *frequency* must be

AEMO | [16 June 2023] Page 47 of 78

⁵² Per-phase RMS quantities for unbalanced Disturbances

⁵³ Measured as a rate of decay of the oscillation – for example, halving time.

- within 5 degrees. This does not apply to rapid events under paragraph (b), but applies to any subsequent oscillations;
- (iv) The timing of the occurrence of the rapid slopes, events or the commencement of oscillations described in paragraphs (a)-(c) must be consistent with the *plant* characteristic that initiates the response⁵⁴.
- (c) Taking into account the *voltage* at the *connection point*, at any point during the simulation, the deviation of the actual measured responses from the simulated response for *active power* and *reactive power* must not exceed 10% of the total change in that quantity for 95% of the samples within the transient window. During periods of oscillatory behaviour, this criterion applies to:
 - The first cycle of the oscillatory response after the transient period (that is, if associated with a fault, then after clearance of the fault and the transient recovery from the fault); and
 - (ii) After the first cycle of the oscillatory response, to the upper and lower bounds of the envelope of the oscillatory response.
- (d) Taking into account the level at which *voltage* settles at the *connection point*, the final *active power* or *reactive power* value at which the *plant* would settle is within the more restrictive of:
 - The final value at which the model response settles ±2% of the plant's maximum capacity; or
 - (ii) The final value at which the model response settles ±10% of the total change in the quantity following the Disturbance.

Where measurement results can be shown to have been affected by changes in supply source (for example, the wind strength for a wind turbine), this shall be taken into consideration when assessing this criterion, so long as sufficient evidence can be shown to demonstrate the cause of the input power change, and in the case of large variations, sufficient efforts were made to re-test the plant to obtain improved measurement results.

Note that for all *plant* closed-loop internal quantities and *production unit* terminal quantities **for aggregated models only**, replace all instances of "95%" in Section 6.2.1 (referring to samples within a transient window) with "90%". *Connection point* quantities do not have this accuracy moderation applied.

If AEMO and the NSP agree that dynamic changes in the *network* or prime mover have contributed to model inaccuracy, they may relax one or more of these accuracy requirements. Additionally, further deviations beyond the model accuracy requirements for *plant* internal quantities may be permitted when direct measurement of internal quantities is not practicable or there are known model deficiencies⁵⁵.

AEMO | [16 June 2023] Page 48 of 78

⁵⁴ This is a difficult criterion to specify, as it depends on what initiates the event or oscillation. Switching events or rapid control actions initiated as a result of passing a threshold level in a measured quantity and any time delays in the design of the *plant* should be straightforward to assess. It is recommended that the fallback criterion for this requirement be that:

⁽i) the response must be explainable; and

⁽ii) any inconsistency in the response should lead to an investigation to establish a plausible reason for the inconsistency. A revision to the model should be considered in the latter circumstance.

⁵⁵ For example, synchronous generation field current.

The accuracy criteria listed above do not apply to IEEE ZIP models or Composite load models, if the use of such models to represent large single loads has been agreed by AEMO and the NSP. For more detailed IBL models, the same accuracy criteria (c) and (d) listed above will apply. The accuracy criteria (a) is only applicable to the synchronous plant components within any single large load. The application of the accuracy criteria (b) is subject to whether the IBL needs to demonstrate compliance to relevant ride through capability performance standards.

6.2.2. Balanced and unbalanced Disturbances

Positive-sequence simulation models are expected to meet the model accuracy requirements specified in Section 6.2.1 for balanced Disturbances. For comparison of the response to different types of unbalanced faults, a positive-sequence model can still be used if it can achieve the required accuracy requirements⁵⁶.

When a positive-sequence model fails to meet the accuracy requirements by a material margin, the use of EMT-type or three-phase RMS simulation models is permissible provided that the simulation model chosen can demonstrate compliance with the model accuracy requirements.

6.2.3. Stable response for the entire intended operating range

The model initialisation and operating range should be consistent with the actual equipment design in regard to the following:

- The entire range of active power.
- The entire range of *reactive power/power factor* (including limits of *reactive power* generation and consumption).

6.2.4. Stable but different response when the response becomes limited

Models must demonstrate accurate and stable behaviour when the limits implemented within the *plant control systems* are reached. For example, activation of a *synchronous plant* under- or over-excitation limiter should not cause model instability, or produce the same response for a scenario where limiters have not been activated. Output of each limiter must be available for plotting to demonstrate that it acts for intended operating conditions, and do not falsely activate when the limit is not reached.

6.2.5. Unstable response when operated beyond its intended operating range

Where *network* conditions, energy source limitations, Disturbances or other factors would cause the *plant* to become unstable, activate protection mechanisms, or otherwise cease operation, it is expected that the model would reflect the *plant's* response. Models should not be created such that they continue to operate stably outside of the *plant's* operating envelope⁵⁷.

6.2.6. No unexpected or uncharacteristic responses

The model must not show characteristics that are not present in the *plant* response, both in terms of the electrical response and modelling numerical artefacts.

AEMO | [16 June 2023] Page 49 of 78

⁵⁶ When using positive-sequence type models for simulation of unbalanced Disturbances, the Applicant must provide information on any possible changes in the model parameters to simulate various types of faults.

⁵⁷ Models that cease output when exposed to conditions outside the intended operating range are not considered inferior, however, the cessation of the model output must not result in instability or crashing of the underlying simulation tool.

6.3. Model validation and confirmation

Each model must be developed and tested to the extent reasonably necessary to establish that it will meet the accuracy requirements. To achieve this:

- During the plant design and development stages, it is expected that the model will be
 rigorously derived from design information and its performance is confirmed against the
 actual plant response; and
- R2 parameters and models must be derived from on-site tests.

Parameters, other than R2, that contribute most significantly to the accuracy of the model for fault, *voltage* and *frequency* Disturbances in the *power system*, must be derived from on-site tests, where possible. Test results from the commissioning tests (used to confirm compliance of the *plant* with *performance standards*) may also provide, or contribute to, R2 data values⁵⁸. These parameters must still be validated (in aggregate) through the validation of the overall performance of the *plant*, *network element*, device, *production unit* or controller to which they pertain.

6.3.1. Model confirmation for plant with limited impact

Where the new or altered *plant* is expected to have limited foreseeable impact on the surrounding *network* and nearby *plant*, model validation requirements may be relaxed by AEMO and the NSP. This could apply to either the scope of model validation tests or the permissible model accuracy requirements.

Confirmation of model performance would consist of the following (to be provided to the NSP and AEMO):

- Factory test results for:
 - Generating or bidirectional unit and energy conversion plant,
 - Control systems, including the energy conversion plant and electricity output control and regulation plant (for example, exciter, automatic voltage regulator [AVR] and Power System Stabiliser [PSS]);
 - Unit transformer;
 - The system transformer (if different from the unit transformers); and
 - Load converter interface, including UPS devices, rectification devices (such as hydrogen electrolysers), and relevant control systems.
- Comparisons of simulations for step response tests against the on-site step response test
 results. This would include tests at several load levels and operation across the relative
 power range, such that:
 - The model response is within the tolerances specified in these Guidelines or tolerances agreed by AEMO and the NSP on a case-by-case basis; and

AEMO | [16 June 2023] Page 50 of 78

⁵⁸ Note that NER S5.2.4(d)(1) specifies that the R2 values must be submitted to AEMO and the NSP within three months of the completion of commissioning.

 Deviations must be reasonably explained and attributed, for example, to the influences of external parameters or differences in pre-test simulation conditions with actual system conditions.

6.3.2. Pre-connection model confirmation

AEMO requires OEM confirmation of the response of their *plant* by factory or laboratory testing where:

- Connections are proposed to parts of the network with low system strength where the standard plant might not be adequate any more;
- When the plant is designed to provide functionality not offered previously; or
- When new *plant* is introduced to the *NEM* with unexpected or inferior modelling responses.

Confirmation of RMS- and EMT-type model adequacy prior to detailed *connection* studies is prudent to minimise risks that may multiply the time and effort in assessing a specific *plant connection* and alterations.

The following principles will apply to pre-connection model confirmation tests:

- Among Disturbances applied for model confirmation tests, there should be a two-phaseground or three-phase fault equivalent to what might be experienced by a *generating unit* or bidirectional unit upon installation. The same should be applied to IBLs which are expected to be compliant with relevant ride through capability performance standards.
- The post-fault fault level and *network* impedances used for the testing should be reasonably representative of, or lower than, the post-fault fault level that the *plant* would experience.
- The individual item of *plant* tested is identical to the ones to be installed.
- The *plant* tested has identical *control system* settings to the one being installed, or the difference in settings can be translated into appropriate model parameter values applicable to the *plant* to be installed.
- The accuracy and adequacy of EMT-type models must be confirmed against the response
 of individual items of *plant*, including *production units* and dynamic *reactive power* support *plant* (if applicable), and IBLs for the conditions specified above, or against the validated
 EMT-type models.
- Changes in the *control systems* or settings of individual items of *plant* are necessary if the submitted EMT-type model exhibits uncharacteristic or unexpected responses.
- Model response should be generally aligned with expected response. The model accuracy requirements set out in Section 6.2.1 will not strictly apply during this stage.
- Where both RMS and EMT models are provided, responses of the two models should be benchmarked against one another in accordance with the Dynamic Model Acceptance Guideline. While the accuracy requirements in Section 6.2.1 will not apply in the absence of actual plant response data, the criteria in this section may be applied as guidance for assessing benchmarking performance with the EMT model response in place of the 'plant' response and the RMS as the 'model' response. Divergences in model responses from the strict criteria should be expected, especially on sub-cycle time scales.
- Tests should be conducted across a range of operating conditions including pre-Disturbance active power and reactive power levels.

AEMO | [16 June 2023] Page 51 of 78

NSPs must provide the range of operating conditions, including pre-Disturbance levels of *active power* and *reactive power* for the required tests to be carried out.

Results obtained from off-site tests or factory tests may be used for model confirmation tests. Another approach adopted by power system equipment manufacturers is Hardware in Loop (HIL) testing to simulated Disturbances well before *plant* undergoes on-site commissioning and R2 model validation.

6.3.3. Post-connection model validation (R2)

R2 model validation is the final stage of providing evidence that the models submitted to AEMO and the NSP are of adequate quality to be used in *power system* studies to determine how to operate the *power system* securely. It is validated by comparing RMS and EMT model response to the *plant* installed at the site of interest.

For each relevant *performance standard* arising out of the technical requirements in NER S5.2.5, Table 6 describes the model validation required from the Applicant for the *plant* in question.

Table 6 Simulation tools required for R2 model validation (generating systems and integrated resource systems)

Clause of the NER	RMS simulation tool	EMT simulation tool	Harmonic analysis tool
S5.2.5.1 – Reactive Power Capability	✓	×	×
S5.2.5.2 – Quality of electricity generated	×	Maybe ^A	✓
S5.2.5.3 – Response to frequency disturbances	✓	×	×
S5.2.5.4 – Response to voltage disturbances	✓	✓	×
S5.2.5.5 – Response to disturbances following contingency events	✓	✓	x
S5.2.5.6 – Quality of electricity generated and continuous uninterrupted operation	x	✓	x
S5.2.5.7 – Partial Load Rejection	✓	×	×
S5.2.5.8 – Protection from power system disturbances	✓	✓	x
S5.2.5.9 – Protection systems that impact on power system security ^B	-	-	-
S5.2.5.10 – Protection to trip plant for unstable operation ^B	-	-	-
S5.2.5.11 - Frequency control	✓	✓	×
S5.2.5.12 - Impact on network capability	✓	×	×
S5.2.5.13 – Voltage and reactive power control	✓	✓	×
S5.2.5.14 – Active Power Control	✓	✓	×

A. If harmonic analysis tool fails to provide the required accuracy. B. Cannot be realistically validated by staged R2 tests.

On-site tests

During commissioning, validation of model performance can be demonstrated by model overlays based on the tests outlined in the R2 test template for synchronous machines⁵⁹ and

AEMO | [16 June 2023] Page 52 of 78

⁵⁹ Available at: https://www.aemo.com.au/-/media/Files/Electricity/NEM/Network_Connections/Transmission-and-Distribution/Generating-System-Test-Plan-Template-for-Conventional-Synchronous-Machines.pdf

asynchronous technologies⁶⁰, and by continuous monitoring described below. For *network* and reactive support *plant*, relevant tests from these templates can be used to demonstrate model performance.

Continuous monitoring of disturbances

Congruence between *plant* and model dynamic responses for some aspects may be difficult to demonstrate until a *network* Disturbance occurs. It is, therefore, necessary that the Applicant develops a continuous monitoring program to demonstrate model accuracy for all major items comprising the *plant* (that is, both at a system and unit level). As part of the compliance program developed in accordance with NER 4.15⁶¹, high speed data collected during a Disturbance can be overlaid to demonstrate correct model responses. The Applicant must submit the model overlays to the NSP and AEMO for analysis and model verification as soon as possible following such a Disturbance.

In the absence of a detailed R2 commissioning process for IBLs, the validation of detailed IBL models may rely on the continuous monitoring of disturbances during the load operation.

6.4. Non-conformance with model accuracy requirements

Where AEMO or NSP determines that model inaccuracy outside the tolerances specified in Section 6.2.1 manifests itself into a risk to *power system security*, adverse impact on the performance of *Network Users*, or inability meet its *performance standards*, the following action may be required by either the NSP or AEMO:

- Additional testing;
- Operational constraints imposed until the modelling issue can be resolved;
- Revised models or parameters verified by pre-commissioning model confirmation tests be submitted and accepted (revision may result in submission of a detailed vendor-specific model); or
- Any combination of these.

These requirements may persist or be repeated until the model accurately reflects the *plant's* response, and hence the *plant's* performance can be adequately predicted by *power system* studies.

Confidentiality of information and models provided

7.1. Storage and use by AEMO

AEMO's personnel have restricted access to data provided to AEMO by *Registered Participants* under the NER on a need-to-know basis.

AEMO | [16 June 2023] Page 53 of 78

⁶⁰ Available at: https://www.aemo.com.au/-/media/Files/Electricity/NEM/Network_Connections/Transmission-and-Distribution/Generating-System-Test-Template-for-Non-Synchronous-Generation.pdf

⁶¹ A compliance program instituted and maintained under NER 4.15(b) must provide reasonable assurance of ongoing compliance with each applicable *performance standard*.

Information obtained by AEMO under the NER⁶² and covered by these Guidelines is stored by AEMO on its systems, while the models so obtained are stored in AEMO's OPDMS for planning, operations, DSA and other applications. All information and models are used for the purpose for which they are intended to be used, consistent with the NER.

7.2. Intellectual property

These Guidelines do not affect the intellectual property rights in the information and models obtained by AEMO under the NER.

7.3. EMT model black-boxing, compilation or encryption

As models can be provided to other *Registered Participants* under the NER, model owners may wish to black-box, compile or otherwise encrypt portions of an EMT model that are commercially sensitive, or where additional intellectual property protection is desired.

Provided the requirements in these Guidelines as to the model's utility are met, and a legitimate user of the model is not hampered in their ability to carry out legitimate studies using the model, black-boxing is acceptable.

Model owners remain responsible for the adequacy of the black-boxing, compilation or other encryption of their model.

7.4. Provision of information and models to third parties

7.4.1. Generally

Requests for models and other information may be directed to AEMO under NER 3.13.3(k) or NER 4.6.6(e). AEMO will manage the disclosure of models and other information held by AEMO in accordance with the NER and will only disclose to the extent it is reasonably necessary for the purpose for which it is requested by a *Registered Participant*.

NER 3.13.3(I) requires AEMO to provide information that is reasonably required by a *Registered Participant* to carry out *power system* simulation studies (including load flow and dynamic simulations) for planning and operational purposes. That information must be treated as *confidential information*⁶³. Registered Participants' confidentiality obligations are set out in NER 8.6.

NER 3.13.3(I5) requires AEMO in certain circumstances to provide *power system* and *generating system* or *integrated resource system* model information to a *Transmission Network Service Provider* (TNSP) for planning and operational purposes which the TNSP must treat as confidential⁶⁴.

AEMO will update and *publish* the register it is required to maintain under NER 3.13.3(p1) to include the fulfilment of all new requests for models and other information.

Table 7 summarises the type of model that AEMO will provide to a *Registered Participant* depending on the nature and reasonableness of the request.

AEMO | [16 June 2023] Page 54 of 78

⁶² See NER S5.5.7(b1)

⁶³ See NER 3.13.3(I)(3).

⁶⁴ See NER 3.13.3(I7).

Table 7 Models to be provided by AEMO

Data Requests	Application	
	System Strength Impact Assessment	Other Power System Simulation Studies
Generator and Integrated Resource Provider data	Not applicable	RMS (full)
Generator, Integrated Resource Provider and MNSP data	EMT (limited) ^A	RMS (full)
NSP data	EMT full	RMS (full) & EMT full
Network User data	EMT full	RMS (full) & EMT full

A. 'Limited' means that the contents of the model will be limited to those strictly necessary for the performance of a full system strength impact assessment, or whether the model was reasonably appropriate for conducting the full system strength impact assessment, as appropriate.

7.4.2. Reasonably required information

NER 3.13.3(k1) requires AEMO to set out in these Guidelines the circumstances in which the information requested under NER 3.13.3(k)(2) to be 'reasonably required' by a *Registered Participant*. The information referred to in NER 3.13.3(k)(2) is information to carry out *power system* simulation studies (including load flow and dynamic simulations) for planning and operational purposes.

The remainder of this Section 7.4.2 details what AEMO considers to be 'reasonably required'.

Generators, Integrated Resource Providers and Network Users

The information required to be provided under NER 3.13.3(I) and (I5) in respect of a *generating* system or integrated resource system is limited to that which AEMO holds and includes:

- The RUG, in unaltered form⁶⁵.
- Model source code, subject to the restrictions in NER 3.13.3(I)(2) and (I4), and permissions in NER 3.13.3(I3).
- Model information reasonably required by a TNSP for planning and operational purposes, subject to the requirements in NER 3.13.3(I6).

Generators, Integrated Resource Providers, Network Users, and Market Network Service Providers affected by a System Strength Impact Assessment

As stipulated by NER 4.6.6(e), where *plant* is subject to a full *system strength impact* assessment, AEMO is required to treat a request for the 'model' referred to in NER 4.6.6(b)(2) as a request under NER 3.13.3(k)(2) and provide the model to:

- The NSP required to carry out the full system strength impact assessment.
- Where only one Applicant is impacted by the system strength impact assessment, to that Applicant.
- Where more than one Applicant is affected by the system strength impact assessment and, provided the NSP required to carry out the system strength impact assessment has complied with Section 4.2.3 of the system strength assessment guidelines, all affected

AEMO | [16 June 2023] Page 55 of 78

⁶⁵ See NER 3.13.3(I)(1).

Applicants to the extent that the impact of neighbouring *plant* (existing or proposed) needs to be accounted for in any new or altered *plant* design.

Network Service Providers

The information required to be provided under NER 3.13.3(I) and (I5) in respect of a *network* or any *network element* is limited to that which AEMO holds and includes:

Model source code, subject to the restrictions in NER 3.13.3(I)(2) and (I6), and permissions in NER 3.13.3(I3).

As specified in NER 3.13.3(I3), historical information, *network* dynamic model parameter values, a *network* model of the *national grid* suitable for load flow and fault studies, and other technical data listed in NER S5.5.3 and S5.5.4.

7.4.3. Confidentiality

Generators, Integrated Resource Providers and Network Users

Any model provided under NER 3.13.3(I) or (I5) remains *confidential information* and can only be used by the recipient for the purpose permitted by NER 3.13.3(k).

Generators, Integrated Resource Providers, Network Users and Market Network Service Providers affected by a System Strength Impact Assessment

Any model provided under NER 4.6.6(e) remains *confidential information* and can only be used by the recipient to:

- In the case of the NSP, carry out the full system strength impact assessment.
- In the case of an Applicant, assess whether the model was reasonably appropriate for conducting the system strength impact assessment.

Network Service Providers

Any model provided under clause 3.13.3(I) and (I5) remains *confidential information* and can only be used by the recipient for the purpose permitted by clause 3.13.3(k).

8. Alternative process

Section 8 describes, where an Applicant cannot provide the required information or model within the prescribed timeframe for a reasonable cost, a process to be followed to give AEMO and the connecting NSP sufficient information to be able to fulfil the purpose for which the information or model is required.

8.1. Generally

Applicants whose *plant* does not meet the exemption criteria in Section 3.3 may apply for a variation to a requirement to provide specified data or models required by these Guidelines using the form contained in Appendix B.

8.2. Examples of requests

To assist *Registered Participants*, AEMO provides the following examples of cases where an application to vary a requirement under these Guidelines might be appropriate:

AEMO | [16 June 2023] Page 56 of 78

- Representation of pump storage and *generation* in the one model where there is no value to be gained by providing multiple models.
- Provision of model source code based on C or C++, rather than Fortran.
- Development by AEMO of a PSCAD™/EMTDC™ model of a synchronous generating unit or synchronous generating system, where no other developer can be found, at the requestor's expense.

8.3. Consideration of request

AEMO must consider a request received in the form contained in Appendix B by reference to the following matters:

- The reasonable costs of efficient compliance by Applicants with these Guidelines and the Data Sheets compared to the likely benefits from the use of the information provided under those;
- Whether the information has been made available to AEMO in the past;
- NSPs' requirements for data and modelling information that is reasonably necessary for them to fulfil their obligations under the NER or jurisdictional electricity legislation;
- The model, and how it should be used;
- The potential impact of the *plant* to be connected on *power system security*;
- Quality of supply to Network Users;
- The calculation of network limits;
- The extent to which changes are expected to affect the operation of the *connection* under consideration;
- The ability for an NSP, AEMO, the Applicant, or any other party allowed under the NER to conduct studies for *connection applications* and access negotiations; and
- Any other matters AEMO considers to be reasonably relevant to a request.

8.4. Determination

Following consideration of the request, AEMO must:

- Accept or reject it;
- Propose options for the Applicant to consider; or
- Request further information.

AEMO | [16 June 2023] Page 57 of 78

Appendix A. Application for exemption from the requirement to provide model and other information

APPLICATION FOR EXEMPTION FROM THE REQUIREMENT TO PROVIDE INFORMATION OR MODELS SPECIFIED IN THE POWER SYSTEM MODEL GUIDELINES

To enable a timely response to your Application please complete all sections of this form. Please use additional pages and attach supporting documentation where required.

Applicant name
Contact Details
Name
Phone
Email
Postal Address
Date of Application
Affected Plant
Size of Plant
Why Applicant should be granted an exemption (based on the grounds detailed in section 3.3 of the Power System Model Guidelines).
Any other relevant information

Please send this application to: connections@aemo.com.au

AEMO | [16 June 2023] Page 58 of 78

Appendix B. Application to provide alternative model or information

APPLICATION TO PROVIDE ALTERNATIVE MODEL OR INFORMATION SPECIFIED IN THE POWER SYSTEM MODEL GUIDELINES

To enable a timely response to your Application please complete all sections of this form. Please use additional pages and attach supporting documentation where required.

Applicant name
Contact Details
Name
Phone
Email
Postal Address
Date of Application
Information or model requirement that cannot be met Include reference to section in the Guidelines where the requirement is specified.
Why the requirement cannot be met. Include: Evidence to substantiate reasons for being unable to meet the requirement; Consideration of how this might affect AEMO or NSP's ability to assess proposed access standards; and Discussion of alternative options considered, sufficient to satisfy the NSP and AEMO that meeting the requirement is technically unachievable.
Proposed Alternative Information or Model to be provided Include a description of the discrepancy between the relevant requirement and what is proposed to be provided and a discussion of how the alternative is a reasonable equivalent of the requirement that cannot be met.
Proposed date by which Alternative Information or Model will be provided

Please send this application to: connections@aemo.com.au

Appendix C. Modelling component requirements

Appendix C sets out components that are required to be included in models based on the *plant*, studies being completed and the tool being used. These tables focus on physical components to be included within models. As load flow and fault level studies are based on Newtonian solution methods, these study types are excluded from all tables in this appendix.

C.1 Definitions and notes

C.1.1 Protection systems

Experience has shown that protective functions of *plant* can have a major impact on stability of the *generating system* or *integrated resource system* and the *power system*. Reference to "protection" in the following table and footnotes includes:

- High and low voltage protection;
- Over- and under-frequency protection;
- Rate of change of frequency protection;
- Multiple fault ride-through protection;
- · Loss of excitation protection;
- Over-flux (V/Hz) protection;
- Out-of-step protection;
- Negative phase sequence (voltage unbalance) protection⁶⁶;
- Reverse active power protection;
- Torsional stress protection⁶⁷;

AEMO | [16 June 2023] Page 60 of 78

⁶⁶ Where the underlying simulation tool allows negative phase sequences to be evaluated.

⁶⁷ This is a relatively uncommon protection relay – the *Generator* must determine whether the exclusion of this relay from the model has a material impact on model accuracy.

- Unit transformer and generator differential protection; and
- Any Remedial Action Schemes that have been deemed to have material impact on the system⁶⁸.

All protection systems included in the models must be consistent with the plant's performance standard.

C.1.2 Control loops

The representation of control loops in converter-connected technology is of particular importance for assessing transient stability of *plant*. Where the following terms are included within tables, the sub-points indicate the control loops that are expected to be represented within the model.

Outer loop converter control

- Active power and reactive power control.
- Active torsional damping (if applicable).
- Fast acting *voltage* control (if applicable).
- Fast acting *frequency* control (if applicable).

Inner control loop

- DC link current control.
- DC link voltage control.
- Rotor-side current control (if applicable).

C.1.3 High-frequency transient models

Only *plant* involved in *power system* restoration, including SRAS sources, are required to provide high-frequency transient models. These models must represent fast- and slow-front transients as defined by the IEC Standard 60071 Part 1.

AEMO | [16 June 2023] Page 61 of 78

⁶⁸ See the Remedial Action Scheme Guidelines for more information.

C.2 Wind generation

- Models to be aggregated as per Section 4.7.
- Measurements feeding into controls must include relevant filtering and delays.
- Winding ratios of VTs and CTs feeding protection mechanisms must be provided.

C.2.1 Turbine model components

Elements marked with an asterisk (*) require the Applicant to determine whether the component needs to be included to accurately represent the *plant* response for the phenomena of interest.

Component Study	Aerodynamics	Pitch controller	Mechanical drive train	Torsional damping	Electrical generator ^A	Dynamic braking resistor / chopper	DC link	IGBT switches and PWM switching	Unit transformer ^B

High-frequency transient	-	-	EMT	EMT	EMT	EMT	-
Harmonics	EMT*	EMT*	EMT	EMT	EMT	EMT	-

A. Including delays that affect performance, controls and outputs for reactive power support plant, controls for active power, reactive power, voltage, power factor and frequency, and any participation in fault ride-through protection.

C.4 Converter-based energy storage systems

- Models to be aggregated as per Section 4.7.
- Measurements feeding into controls must include relevant filtering and delays.
- Winding ratios of VTs and CTs feeding protection mechanisms must be provided.

C.4.1 Converter model components

Elements marked with an asterisk (*) require the Applicant to determine whether the component needs to be included to accurately represent the plant response for the phenomena of interest.

AEMO | [16 June 2023] Page 65 of 78

B. Details of switching philosophy to be provided in the RUG.

C. Including full voltage controller representation and relevant protection mechanisms.

D. Including saturation for EMT models.

Component	Energy storage (battery, super- capacitor)	DC-DC converter	DC link	IGBT switches	PWM switching	Unit transformer ^A	Internal filters
Transient Stability	EMT*	RMS, EMT	RMS, EMT	-	-	RMS, EMT	RMS, EMT

Harmonics	EMT	EMT	EMT	EMT	-	-	-	-

AEMO | [16 June 2023] Page 66 of 78

A. Explicit representation.
B. Including *frequency* raise and lower, *frequency* droop and deadbands.

C.4.2 Balance of plant model components

Component	Park controller ^A	Other coordinated control systems	Reticulation Network	Static reactive support plant ^B	Dynamic reactive support plant ^c	Connection point transformers ^D	Transformer onload tap changer controllers
Transient Stability	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT
Sub-synchronous interactions	EMT	EMT	EMT	EMT	EMT	EMT	-
High-frequency transient	-	-	EMT	EMT	EMT	EMT	-
Harmonics	EMT*	EMT*	EMT	EMT	EMT	EMT	-

A. Including delays that affect performance, controls and outputs for reactive power support plant, controls for active power, reactive power, reactive power factor and frequency, and any participation in fault ride-through protection.

C.5 Inverter-based load

- Models to be aggregated as per Section 4.7.
- Measurements feeding into controls must include relevant filtering and delays.
- Winding ratios of VTs and CTs feeding protection mechanisms must be provided.
- Inclusion of model components depends on actual load configuration.
- Apply to detailed load models only (not applicable to IEEE ZIP or Composite load model)

C.5.1 Converter model components

Elements marked with an asterisk (*) require the Applicant to determine whether the component needs to be included to accurately represent the plant response for the phenomena of interest.

AEMO | [16 June 2023] Page 67 of 78

B. Details of switching philosophy to be provided in the RUG.

C. Including full voltage controller representation and relevant protection mechanisms.

D. Including saturation for EMT models.

Component	Energy storage (battery, super- capacitor)	DC-DC converter	DC link	IGBT switches	PWM switching	Unit transformer ^A	Internal filters
Transient Stability	EMT*	RMS, EMT	RMS, EMT	-	-	RMS, EMT	RMS, EMT

Harmonics	EMT	EMT	EMT	EMT	-	-	-	-

AEMO | [16 June 2023] Page 68 of 78

A. Explicit representation.
B. Including frequency raise and lower, frequency droop and deadbands.

C.5.2 Balance of plant model component

Component	Park controller ^A	Other coordinated control systems	Reticulation Network	Static reactive support plant ^B	Dynamic reactive support plant ^c	Connection point transformers ^D	Transformer onload tap changer controllers
Transient Stability	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT
Sub-synchronous interactions	EMT	EMT	EMT	EMT	EMT	EMT	-
High-frequency transient	-	-	EMT	EMT	EMT	EMT	-
Harmonics	EMT*	EMT*	EMT	EMT	EMT	EMT	-

A. Including delays that affect performance, controls and outputs for reactive power support plant, controls for active power, reactive power, voltage, power factor and frequency, and any participation in fault ride-through protection.

C.6 High voltage DC link

- Measurements feeding into controls must include relevant filtering and delays.
- Winding ratios of VTs and CTs feeding protection mechanisms must be provided.

C.6.1 Inverter/rectifier model components

Elements marked with an asterisk (*) require the Applicant to determine whether the component needs to be included to accurately represent the *plant* response for the phenomena of interest.

AEMO | [16 June 2023] Page 69 of 78

B. Details of switching philosophy to be provided in the RUG.

C. Including full *voltage* controller representation and relevant protection mechanisms.

D. Including saturation for EMT models.

Component	HVDC cable/line	IGBT switches / thyristors	PWM switching / firing pulses	AC and DC filters	Link transformer ^A	Static reactive support plant ^B	Dynamic reactive support plant ^c	Transformer onload tap changer controllers
Transient Stability	RMS, EMT	EMT	EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT

High-frequency transient	EMT*	EMT*	EMT*	-	EMT	-	-	-	EMT
Harmonics	EMT	EMT	EMT	EMT	-	-	EMT*	-	-

A. Explicit representation.

C.7 Synchronous machines and generators

- Measurements feeding into controls must include relevant filtering and delays.
- Winding ratios of VTs and CTs feeding protection mechanisms must be provided.

AEMO | [16 June 2023] Page 70 of 78

B. Details of switching philosophy to be provided in the RUG.

B. Including *frequency* raise and lower, *frequency* droop and deadbands.

C.7.1 Generator model components

Elements marked with an asterisk (*) require the Applicant to determine whether the component needs to be included to accurately represent the *plant* response for the phenomena of interest.

Component	Generator ^A	Mechanical drive train (inc. turbine, flywheel etc.)	Torsional damping	Governor ^B	Power system stabiliser	Unit transformer ^c	Exciter	Automatic voltage regulator ^D
Transient Stability	RMS, EMT	EMT*	EMT*	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT
Sub-synchronous interactions	EMT	EMT	EMT	EMT	EMT	EMT	EMT	EMT
High-frequency transient	EMT	-	-	EMT	EMT	EMT	EMT	EMT
Harmonics	EMT	-	-	-	-	EMT	EMT	EMT

A. Full saturation curve required for EMT models.

D. Including compensator and derived measurements.

Component	Excitation limiters ^A	Transformer onload tap changer controllers	Multiple fault ride-through limitations	Protection
Study				
Transient Stability	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT
Sub-synchronous interactions	EMT	-	-	EMT
High-frequency transient	EMT	-	-	EMT
Harmonics	EMT	-	-	-

A. Including all applicable limiters in over- and under-excited range (e.g over-excitation limiter, under-excitation limiter, V/Hz limiter, PQ limiters etc.).

C.8 Converter-based reactive support systems

- Including SVCs, STATCOMs.
- Measurements feeding into controls must include relevant filtering and delays.

AEMO | [16 June 2023] Page 71 of 78

B. Including frequency control, droop, deadbands and isochronous mode.

C. Including saturation characteristics for EMT models.

• Winding ratios of VTs and CTs feeding protection mechanisms must be provided.

C.8.1 Reactive support model components

Elements marked with an asterisk (*) require the Applicant to determine whether the component needs to be included to accurately represent the *plant* response for the phenomena of interest.

Component	DC link componentry	Thyristor / IGBT switches	PWM switching / firing control	Unit transformer ^A	Internal filters	External shunt devices and filters ^B
Transient Stability	EMT*	-	-	RMS, EMT	RMS, EMT	RMS, EMT
Sub-synchronous interactions	-	-	-	EMT	EMT	EMT
High-frequency transient	-	EMT	EMT	EMT	EMT	EMT
Harmonics	-	EMT	EMT	EMT	EMT	EMT

A. Including saturation for EMT models.

B. Including any control of external shunts from *plant* controller.

Component	Inner loop converter control	Outer loop converter control	Phase locked loop ^A	Frequency control ^B	Power oscillation damping control	High voltage ride-through	Low voltage ride-through	Multiple fault ride- through limitations	Protection
Transient Stability	EMT	RMS, EMT	EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT	RMS, EMT
Sub-synchronous interactions	EMT	EMT	EMT	EMT	EMT	EMT	EMT	-	EMT
High-frequency transient	EMT*	EMT*	EMT*	-	EMT	EMT	-	-	EMT
Harmonics	EMT	EMT	EMT	EMT	EMT	-	-	-	-

A. Explicit representation.

B. Including frequency raise and lower, frequency droop and deadbands.

Appendix D. Quantities to be assessed for transient and voltage analysis

The following table outlines the quantities that have the accuracy requirements of Section 6.2 applied, based on the test or Disturbance of interest. Quantities that are not applicable to the *plant* under consideration should be ignored (for example, field *voltage* for a photovoltaic inverter). The accuracy of EMT model responses is evaluated on their simulation-tool calculated RMS quantities, with filtering appropriate for a 50 Hz nominal system.

Test / Disturbance	Perturbed quantity	Measured quantity		
Voltage Reference Step	Voltage reference (production unit or centralised controller)	Plant terminal active power		
Dawer Factor Deference Ston	Down factor reference (production unit or controlled controller)	Plant terminal reactive power		
Power Factor Reference Step	Power factor reference (production unit or centralised controller)	Connection point active power		
Reactive Power Reference Step	Reactive power reference (production unit or centralised controller)	Connection point reactive power		
Active Power Reference Step	Active power reference (production unit or centralised controller)	Centralised controller dispatch Pref		
Active Fower Reference Step	Active power reference (<i>production unit</i> of centralised controller)	Centralised controller dispatch Qref		
External Voltage Step	Switched shunt, transformer tap, or other external voltage change	Field voltage		
		Field current (EMT only)		
		Relevant limiter output		
		Stabiliser output		
		AVR output		
		Stator voltage		
		Plant terminal voltage		
		Connection point voltage		
		Centralised controller dispatch Vref		
Energy Source Change	Wind speed or solar irradiance	Plant terminal active power		
		Plant terminal reactive power		
		Connection point active power		
		Connection point reactive power		
		Centralised controller dispatch Pref		
		Centralised controller dispatch Qref		
		Plant terminal voltage		
		Connection point voltage		

AEMO | [16 June 2023] Page 73 of 78

Test / Disturbance	Perturbed quantity	Measured quantity		
		Centralised controller dispatch Vref		
External Voltage Angle Step	Voltage angle	Plant terminal active power		
		Plant terminal reactive power		
		Point of Connection active power		
		Point of Connection reactive power		
		Centralised controller dispatch Pref		
		Centralised controller dispatch Qref		
		Field voltage		
		Field current (EMT only)		
		Rotor Angle		
		Stabiliser output		
		Stator voltage		
		Plant terminal voltage		
		Point of Connection voltage		
		Centralised controller dispatch Vref		
Voltage Disturbance	Connection point voltage (network fault)	Plant terminal active power		
		Plant terminal reactive power		
		Point of Connection active power		
		Point of Connection reactive power		
		Centralised controller dispatch Pref		
		Centralised controller dispatch Qref		
		Field voltage		
		Field current (EMT only)		
		Rotor Angle		
		Stabiliser output		
		Stator voltage		
		Relevant limiter output		
		AVR output		
		Plant terminal voltage		
		Point of Connection voltage		

Test / Disturbance	Perturbed quantity	Measured quantity
		Centralised controller dispatch Vref
Frequency Disturbance	Connection point frequency (network event)	Plant terminal active power
External Frequency change	Production unit or centralised controller frequency bias injection	Centralised controller dispatch Pref
		Stabiliser output
		AVR output
		Governor control output
		Governor valve position
		Relevant limiter output

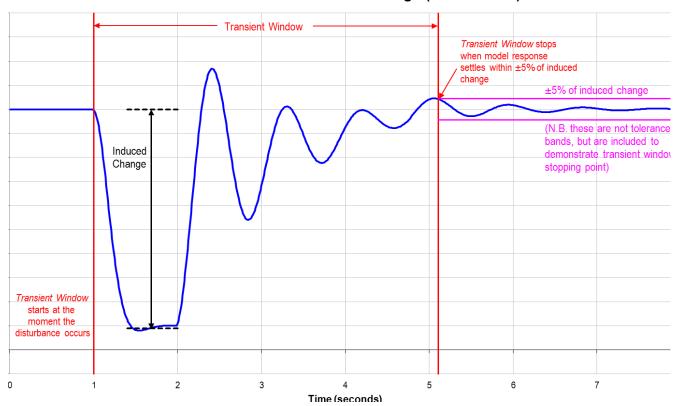

Appendix E. Transient window definitions

The transient window definition is based on the model response, as the model will likely return to a clear Steady State, while due to natural network fluctuations the Steady State of the *plant's* measured response may be more difficult to discern.

Due to the inherently varied nature of transient responses, the following are provided as a guide only.

E.1 Transient window for an uncontrolled change

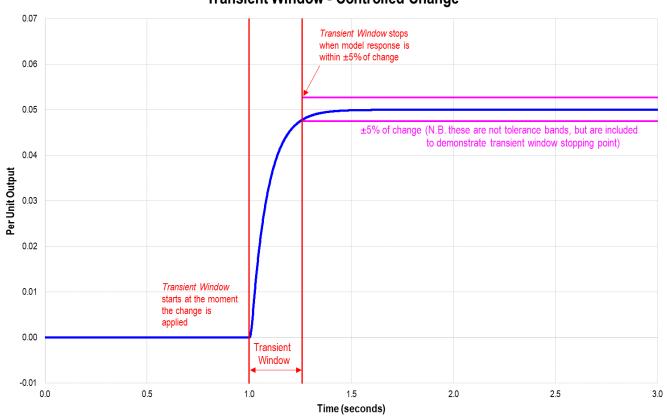

Transient Window - Uncontrolled Change (Disturbance)

E.2 Transient window for a controlled change

Transient Window - Controlled Change

Version release history

Version	Effective date	Summary of changes
1.0	1 July 2018	First version following Final Determination
